Advanced Graphics 2016/2017 – Assignment 2

Introduction

The goal of this assignment is to extend the framework you built in assignment 1 with acceleration structure construction and traversal. A successful implementation greatly reduces the cost of ray / scene intersection, and potentially enables real-time rendering using ray tracing.

For this assignment, it is assumed that the BVH is initially deployed in a Whitted-style ray tracer. It can therefore be assumed that ray distributions have certain characteristics that can be exploited to further enhance ray / scene intersection performance.

BVH construction

The recommended acceleration structure for this assignment is the Bounding Volume Hierarchy (see “Freedom” below). An efficient BVH uses a compact node structure, aligned to cache lines to reduce memory traffic during traversal (see “Language Notes” below). Efficient construction is achieved by using a binning builder, as described by Wald [1]. A high quality BVH is obtained by considering spatial splits, as proposed by Stich et al. [2].

BVH traversal

Traversing the BVH is a straightforward process. A naïve implementation can be optimized using a custom stack rather than recursion, and by using efficient ray/AABB and ray/triangle intersection code.

Performance can be significantly enhanced further by using packet traversal. This can be implemented efficiently using the algorithms proposed by Overbeck et al. [3]. In C++, these algorithms benefit from SIMD / AVX; this may also be possible in C#.

Language Notes

This assignment may be executed in a programming language of choice. Support on the implementation side will be mostly limited to C++ and C# however, and performance is expected to be optimal for C++ code. Choice of programming language will not play a role in grading.

Freedom

Most of the concepts discussed in the lectures apply to BVHs and kD-trees. You are free to use either data structure. You may also propose an alternative data structure, if you wish to explore the specifics of that option. Please discuss your plans with me in advance.

You also have a certain level of freedom in the functionality you actually implement. Generally speaking, you can opt for excellence in BVH quality, construction speed or traversal speed to receive a high grade for this assignment.

Practical Details

The deadline for this assignment is Thursday December 22, 23.59. You can hand in your assignment using the Submit system. The materials to submit are:

- your project, including sources and build instructions (if these are not obvious);
- a brief report, detailing implemented functionality, division of work, references and other information relevant to grading your submission.

As discussed, you may work on this assignment alone, or with one other student.
Feel free to discuss practical details on Slack. You are not supposed to share complete ray tracers there, but if everyone uses the same optimal ray/AABB test, that would be considered ‘research’.

**Tasks & Grading**

A passing grade (6) for this assignment requires:

- implementing a correct BVH over a large (>10k) set of input triangles or other primitives, using the surface area heuristic [4] to determine good locations for split planes;
- implementing ray/scene intersection using this BVH;
- achieving a performance improvement over brute force scene intersections in line with expectations.

To obtain an 8, chose one of the following:

1. Construct a high quality BVH by implementing the SBVH construction algorithm, including “unsplitting”. Details are in the paper.
2. Construct a BVH for dynamic scenery using specialized builders for various types of animation. Add a top-level BVH to combine the resulting sub-BVHs, and adapt your traversal code to handle rigid motion.
3. Implement packet traversal for primary and secondary rays using *ranged traversal* and *partition traversal*.
4. If you have something specific that you want to work on but it is not covered by 1..3, please talk to me.

To obtain a 10, pick at least two from the list.

**Purpose**

We will use the result of this assignment in the third assignment. Regardless of the rendering algorithm you will be working on, fast intersection is crucial and allows you to work on something more interesting than a couple of spheres.

May the Light be with you,

- Jacco.
