Final report of CATCH project WITCHCRAFT

1 General information

1.1 Title research project

Title: WITCHCRAFT - What Is Topical in Cultural Heritage: Content-based Retrieval Among Folksong Tunes

Projectnumber: 640.003.501

1.2 Project leaders (university/cultural heritage)

Name: Dr. F. Wiering
Affiliation: Universiteit Utrecht

Name co-project leader(s): Prof. dr. L.P. Grijp
Affiliation: Meertens Instituut

Name co-project leader(s): Prof. dr. R.C. Veltkamp
Affiliation(s): Universiteit Utrecht

1.3 Project participants

Name: Dr. J. Garbers
Affiliation: Universiteit Utrecht
Position: Wetenschappelijk progammeur
Start date: 01-05-2006
End date: 01-05-2010

Name: Drs. ir. P. van Kranenburg
Affiliation: Universiteit Utrecht
Position: Aio
Start date: 01-05-2006
End date: 01-05-2010

Name: Dr. A. Volk-Fleischer
Affiliation: Universiteit Utrecht
Position: Postdoc
Start date: 01-05-2006
End date: 01-02-2010

2 Research plan

2.1 Aims and objectives of the research project

(as described in the original grant application)

The WITCHCRAFT project sets as its objective to develop a fully-functional content-based retrieval system for folksong melodies stored as audio and/or notation, building on the best practices of Music Information Retrieval (MIR) research. More precisely, the project aim is the design, implementation and evaluation of a melody search engine that:

- is capable of handling large amounts of audio and notation data;
- matches relevant low-level *and* high-level musical features using similarity measure(s) that are based on music cognition and perception and reflect the musical characteristics of the folksong repertoire, including oral transmission;
- orders search output (melodies or melody fragments) by musical similarity;
- is usable for both specialists and the general public.

This system's potential will be demonstrated by **integrating** it in the *Nederlandse Liederenbank* of the Meertens Instituut, and adding a selection of early 20th century entertainment/ popular songs from the collection of the Theater Instituut Nederland to test the strengths of the melody search engine in cross-repertoire research.

2.2 Changes with respect to the original research plan

(if applicable)

After initial experiments with audio transcription on the folksong data it appeared that the quality of the output was too low to be used directly in the melody search engine. Therefore we decided to concentrate on searching encoded music notation, and to link audio files to the encodings.

Tools for large-scale data entry and management were created to support the parallel Senter Novem-funded project, Dutch Songs as Musical Content, which in turn provided an unexpectedly large corpus of encoded melodies to WITCHCRAFT. As a consequence, it was unnecessary to incorporate materials from the collection of the Theater Instituut Nederland, which moreover proved to be problematic for organisational reasons.

3 Results

3.1 Scientific results and research highlights (max. 750 words)

Include, in non-scientific language, the most important research highlights of the project.

The WITCHCRAFT project brought together specialists from two areas and two institutions: music information retrieval (MIR), represented by Utrecht University's Department of Information and Computing Sciences, and folk song research, represented by the DOC Lied of the Meertens Institute. The project's objective, the creation of a fully functional content-based retrieval system for folksong melodies, has benefited greatly from the availability of two important resources at the Meertens Institute. The first, *Onder de Groene Linde*, is a collection of more than 7000 field recordings of Dutch folk songs, mostly ballads. Additionally, there are c. 5000 hand-written expert transcriptions of these songs in music notation and very rich metadata. These metadata are stored in a much larger second resource, the *Nederlandse Liederenbank* (Dutch Song Database), containing information about 125.000 songs in the Dutch language. Parallel to the WITCHCRAFT project, the Liederenbank was made available online (http://www.liederenbank.nl) and the folksong materials were integrated into it. At the end of the WITCHCRAFT project, the melody search engine was integrated into the Liederenbank as well (http://www.liederenbank.nl/index.php?wc=true).

As this search engine operates on encoded music notation, a workflow for the production of such encodings was set up. Data entry is done through the WITCHCRAFT editor, which outputs the melody in several formats (Humdrum, MIDI and Lilypond) that are suitable for display, playback and analysis. Initially, only a small test corpus was encoded, but at the end of the project around 5800 encoded melodies had become available through various means.

An important concept in folk song research is the 'tune family', a group of melodies with a presumed common historical origin. An intrinsic difficulty in applying this concept to folk songs is that there is very often no documentary evidence to reason from, so in practice melody norm assignment is based on the assessment of musical (and textual) *similarity*. Tune families can be used as a ground truth for the evaluation of retrieval methods as follows. If one melody is taken from the tune family and used as a query, the most successful retrieval method is the one that gives, in a Google-like list of ranked output, the highest ranks to the other family members. The scientific task then becomes to create the most suitable retrieval method for musical similarity.

Tune family assignation is a complex task performed by experts. In order to understand this task better, an annotation method was developed in close collaboration with the domain experts, by which they could record the features on which they based their decisions, and to what extent. Such annotations were created for 360 melodies and have been used in the design a number of alignment methods. The Annotated Corpus is available to other researchers as well.

Various approaches were designed and tested in the creation of a suitable similarity measure. One that did not work was classification using global features (for example the frequency of an interval in a melody). Other methods, such as the Earth Mover's Distance, Graph Matching and Inner Metric Analysis (IMA), met with only limited success.

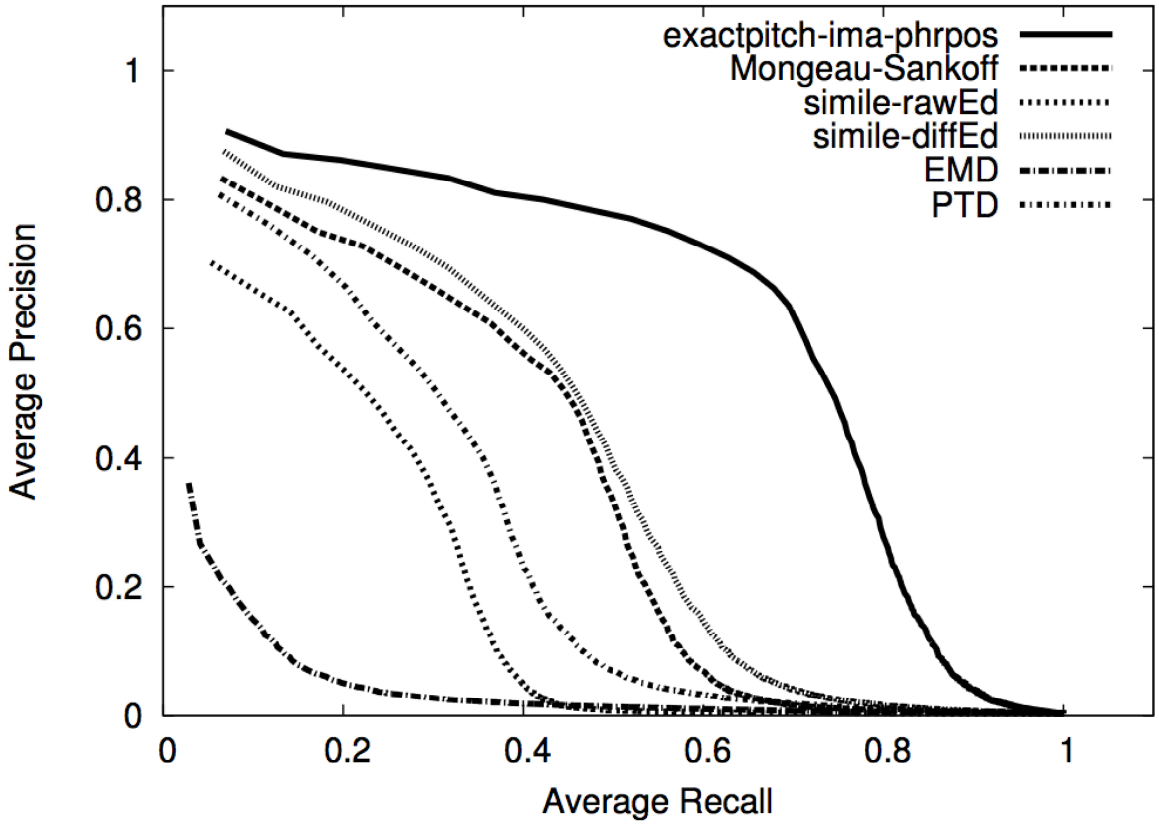
Several promising new avenues were explored. One is 'group querying', a method for relevance feedback in which several related melodies that have already been found are aligned and used to find other members of the same tune family. Another is based on musical audio: after (approximate) transcription and segmentation, the most representative segments for a tune family are identified. Query melodies can be classified by comparison to these segments with reasonable success.

In the end, sequence alignment methods for encoded notation proved to be most successful. Such methods compare two strings of symbols by calculating the cost of inserting, deleting or substituting symbols (here: notes). When applied to folk songs, the aim is to choose these costs in such a way that the more likely a change is to occur within a tune family, the smaller the cost is. The most effective solution that emerged from the research uses a combination of three musical properties, namely pitch, metric weight using IMA, and phrase position. This method was evaluated for musicological usefulness by using it to classify 111 'hard' melodies that so far experts had been unable to assign to a tune family. About one third of these could be classified using the search engine; for one third some relationship to other melodies could be identified. This shows that an important requirement for interdisciplinary collaboration has been fulfilled in this project, namely that results attained in one domain are indeed meaningful in the other domain.

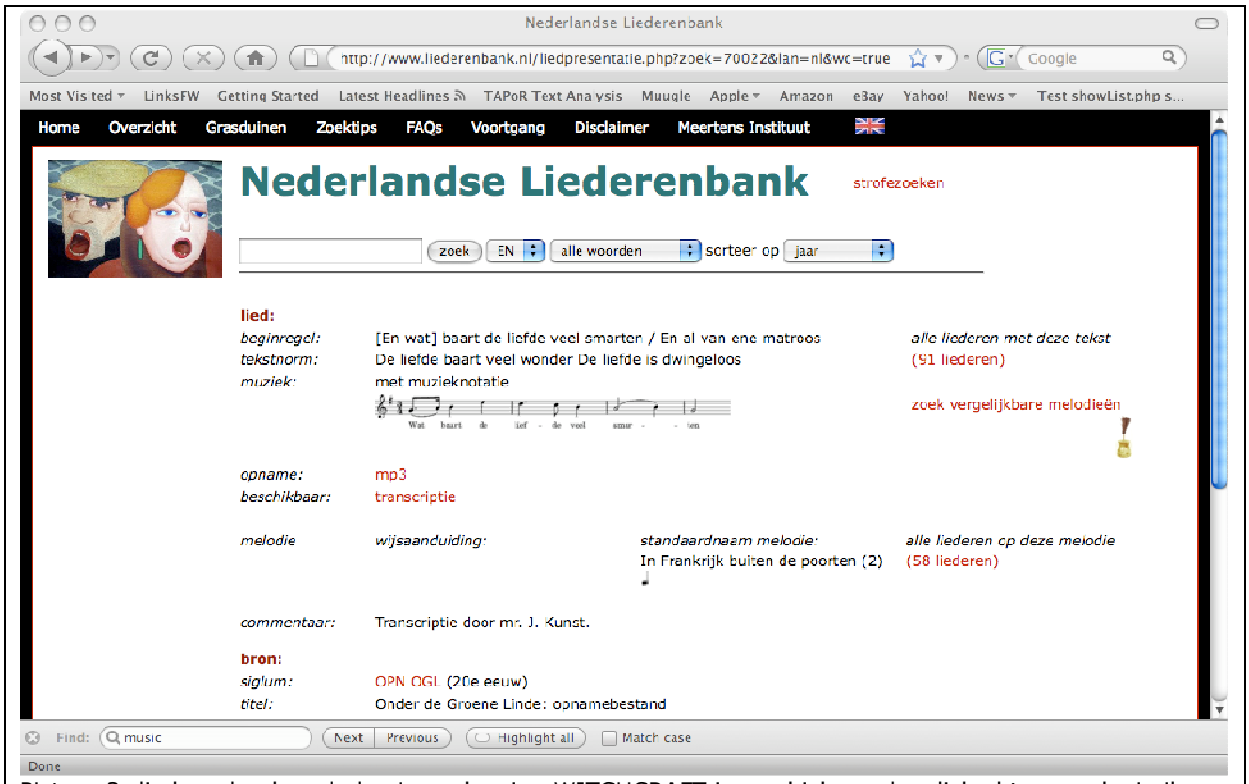
3.2 Pictures of highlights

Attach at least two representative pictures of your research highlights and give a short description of these pictures.

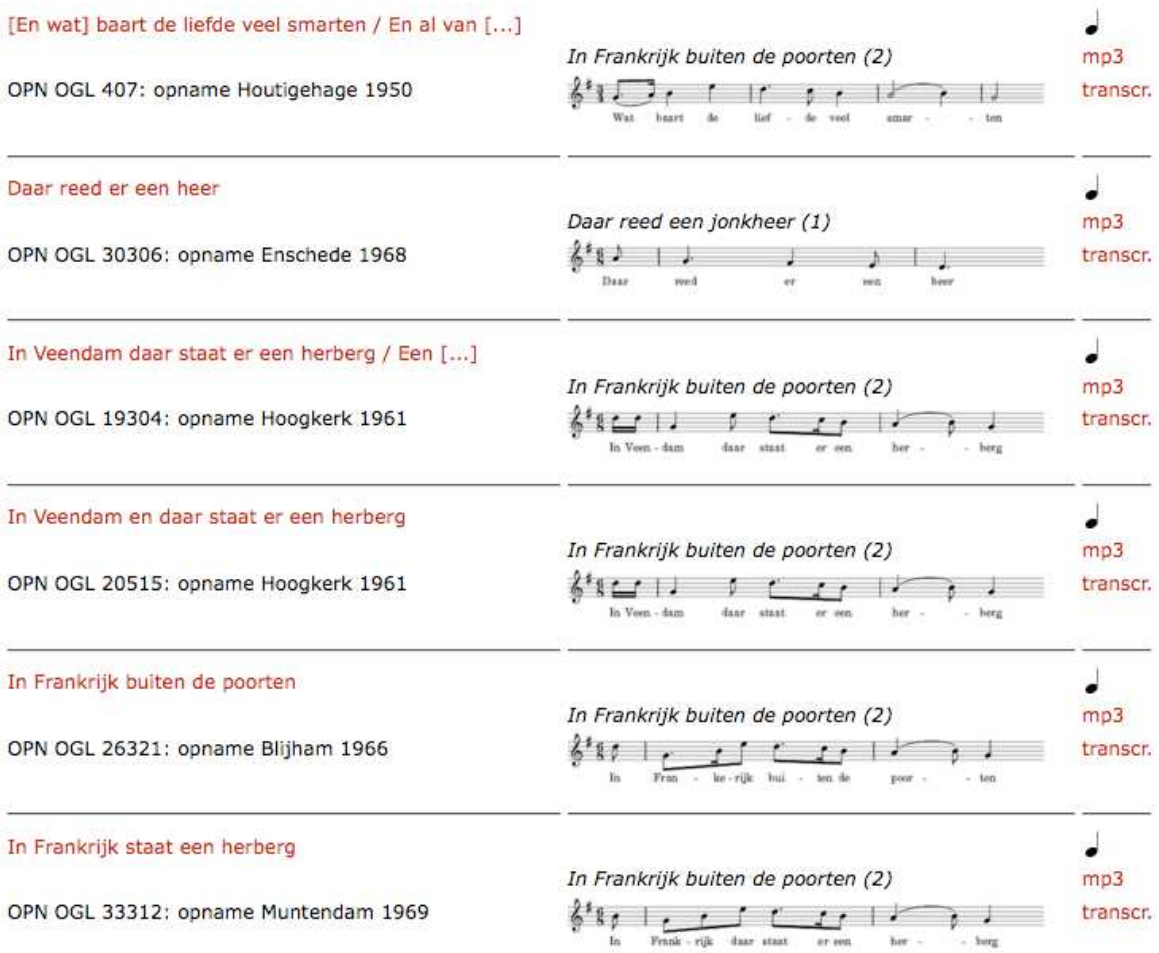
Picture 1: example alignment of two melodies



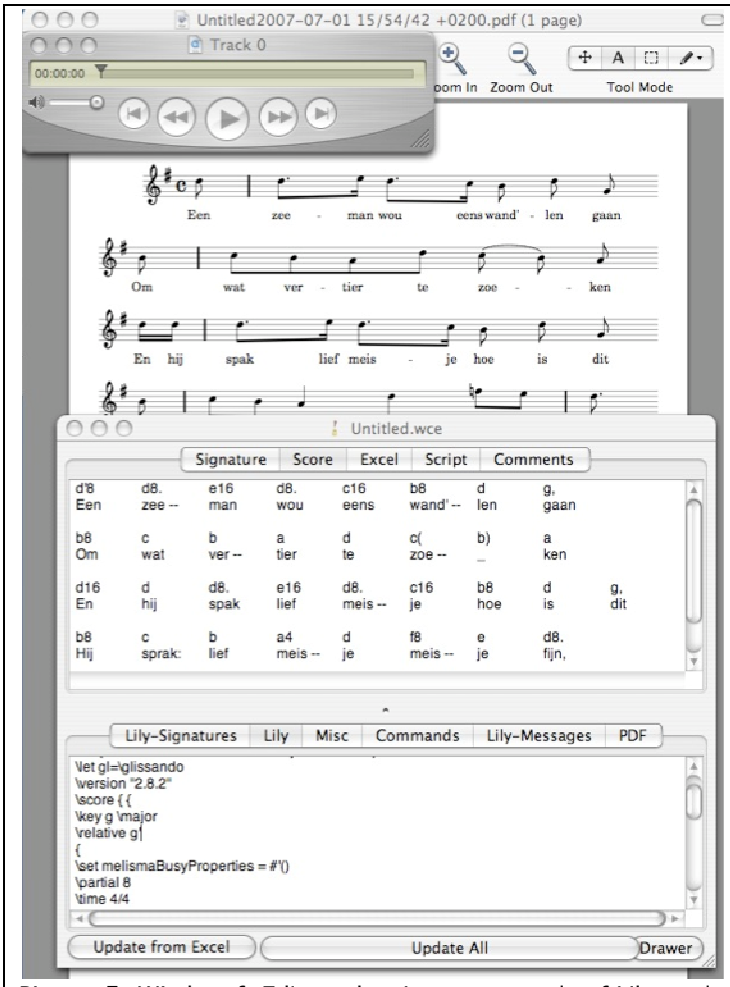
Picture 2: precision-recall graph comparing different melody retrieval methods. The best performing one, exactpitch-ima-phrpos, is the one selected for the Liederenbank.



Picture 3: liederenbank melody view, showing WITCHCRAFT icon which can be clicked to search similar melodies.



Picture 4: result list, after clicking WITCHCRAFT icon



Picture 5: Witchcraft Editor, showing an example of Lilypond encoding just below the middle.

3.3 (Potential) applicability of research results

Mention (potential) areas of application of the results of your research project.

The collaboration model designed for this project is not particular to folksong research but can be generalised to any computer science-humanities collaboration. It is aimed at 'deep' interdisciplinary collaboration, beyond a mere exchange of data and tools, in which research results attained in one disciplinary context contribute to insight in the other discipline.

The data entry workflow tools and melody retrieval methods designed in WITCHCRAFT can be applied to other collections of musical heritage as well. New folk song projects may benefit from both; but existing projects usually focus on digitisation and encoding, and may be particularly interested in content-based retrieval methods. In historical musicology, several source databases and online scholarly edition projects exist to which these methods are applicable as well (e.g. RISM, CMME).

In the area of Music Information Retrieval, this research is part of a trend to move away from low-level features to ones that are closer to the listener's experience of music. This trend is now also reaching the music industry. Popular applications such as Shazam work with identification methods and metadata only, and are consequently still unable to deal with similar but non-identical music. This is especially true for music that is in the 'long tail': if the industry wishes to deal satisfactory with this materials, content-based retrieval methods similar to the ones designed in the WITCHCRAFT project will be needed.

3.4 Publications and other output

Events

Symposium Perspectives for Computational Musicology. Amsterdam, Meertens Institute, 5 October 2010.

11th International Society for Music Information Retrieval Conference (ISMIR 2010), Utrecht, 9-13 August 2010.

Utrecht Summer school in Music Information Retrieval (USMIR). Utrecht Univerity, 2-6 August 2010.

Knowledge representation for intelligent music processing, Dagstuhl Seminar 09051, January 2009

MIR Symposium and Workshop, Utrecht University, 20 February 2007.
CATCH Meeting, Meertens Instituut, 27 April 2007.
International Musicological Society Study Group Meeting on Musical Data and Computer Applications. Zürich, 9-10 July 2007

4 Results of interest to the general public

Please give an up-to-date summary of the project, in Dutch, in language accessible to the general public. EW may use this summary for publicity. Include the objective and problem definition/assignment, and the design. Then give a concise description, in Dutch, of the results achieved/new insights gained in the project.

Het Meertens Instituut herbergt onder de naam *Onder de groene linde* een waardevolle collectie van ruim 7000 opnames van Nederlandse volksliederen. Sinds juni 2007 zijn de opnames publiek toegankelijk via de website van de *Nederlandse liederenbank* (www.liederenbank.nl). Om een bepaald liedje te vinden kan in de liederenbank in metadata (zoals titel, zanger, opnamedatum, etc.) worden gezocht. Het zou nuttig zijn om ook op melodische inhoud te zoeken. Daarom is in kader van het WITCHCRAFT-project gezamenlijk door Meertens Instituut en Universiteit Utrecht een melodieënzoekmachine ontwikkeld.

Een belangrijk begrip uit de melodieleer is *tune family*. Hiermee wordt een groep melodieën aangeduid die als variant van elkaar kunnen worden beschouwd. Gegeven een melodie uit een tune family moet een effectieve melodieënzoekmachine andere leden van de tune family een hoge ranking kunnen geven in een Google-achtige resultaatlijst.

De meest succesvolle methode voor het vinden van gelijkende melodieën is gebaseerd op uitlijning van reeksen symbolen. Er bestaat een algoritme dat de optimale uitlijning van twee reeksen symbolen kan bepalen door de 'kosten' van de uitlijning te berekenen. In de gekozen methode worden de kosten berekend op basis van drie muzikale kenmerken: toonhoogte, ritme en frasestructuur.

Bij een test met 360 zoekvragen en een collectie van bijna 5000 melodieën bleek dat in 90% van de gevallen een relevant zoekresultaat bovenaan de resultaatlijst stond en dat zich in 99% van de gevallen een relevant zoekresultaat bij de eerste 10 melodieën van de resultaatlijst bevindt. Deze methode is als prototype in de Nederlandse liederenbank opgenomen.

5 Follow-up

5.1 Personnel

In what field and in what position do project participants work after the project is finished?

dr. Jörg Garbers: currently unemployed.
dr. ir. Peter van Kranenburg: researcher at the Meertens Institute, Amsterdam, active in computational folk song research.
dr. Anja Volk: has just received a VIDI grant for computational musicology; she will be employed at Department of Information and Computer Sciences, Utrecht University

5.2 Research

Will there be any follow-up of the research performed within the project? In what direction/form?

The follow-up of the WITCHCRAFT project includes:

Anja Volk's VIDI project *Modelling musical similarity over time through the variation principle* (2011-2016), which will be based at Information and Computer Science, Utrecht University. One of the case studies involves folksong.

Computational folksong research at the Meertens Institute into computational modelling of musical memory and oral transmission and into the identification of high-level meaningful patterns in melody. Funding applications are being prepared for this research.

Tools created in the WITCHCRAFT project are being further developed into reliable, robust and usable tools in the WITCHCRAFT Plus project, enabling better access to folk song collections by end users and music researchers. It will also finalize the integration of the melody search engine into the Nederlandse Liederenbank.

Other project initiatives are in preparation with various Dutch and international partners in the areas of computational folksong research, interoperability with other collections of musical heritage (e.g. broadcasting archives) and research into music similarity measures that better capture the cognition and human experience of music.

5.3 Retrospect

Mention experiences, "lessons learned" of consequence for future CATCH-projects

The availability of a generous quantity of high-quality data prepared and annotated by experts was crucial for the success of WITCHCRAFT. Generally, the importance of such data cannot be overemphasised for any form of computational research into digital cultural heritage or humanities, and means should be provided to enable the creation and/or acquisition of such data as part of, or in parallel to the research projects.

Communication between computer scientists and domain experts/musicologists was a complex issue. Even though the parties involved had discussed the topic years in advance, mutual understanding was sometimes difficult to reach. The solution we found was to make reaching this understanding part of the project. This has resulted in a model for cooperation between computer scientists and domain experts, and in insight in how domain experts conceptualise their area of expertise and reach their decisions.

Computer science research produces methods and implementations that can act as a proof of concept. To make these suitable for domain experts and end users is a complex task, involving for example provisions for adequate data management, and dealing with additional requirements of content features, usability and robustness. These issues can only be partially addressed in a scientific research context. It is an important contribution to the impact of CATCH projects that further tool development is supported by CATCH Plus, but it is unfortunate that the actual progress of CATCH Plus is hampered by so many factors that have only little to do with the actual content of the implementation projects.

It was critically important for the success of WITCHCRAFT to work with a cultural heritage institution (the Meertens Institute) that was strongly committed to supporting the project and using its outcomes. This made the practical results of the project fit in a larger context. In particularly, the ongoing work on the Nederlandse Liederenbank, especially its online version, was very beneficial to the project.

5.4 Suggestions for further research

Provide suggestions for further research

In the domain of computational musicology, folk song research in particular:

- suitable audio transcription and analysis methods
- content creation methods, in particular for digital scholarly editions
- interoperability between European collections
- visualisation of song/composition relationships, especially using geographical and temporal information
- computational modelling of musical memory and oral transmission
- quantitative study of musical style and influence

In the domain of music information retrieval:

- designing music retrieval methods that better capture the cognition and human experience of music, notably by addessing 'hooks', salient, meaningful and easily memorised patterns in music
- user studies into musically meaningful features using Web 2.0 methods
- segmentation and pattern discovery models
- integration of audio and notation retrieval approaches
- methods for searching distributed collections
- copyright issues in unlocking music collections
