A PROOF SYSTEM FOR COMMUNICATING SEQUENTIAL PROCESSES (*)

by

Krzysztof R. Apt (1)

Nissim Francez (2)

Willem P. de Roever (3)

ABSTRACT: An axiomatic proof system is presented for proving partial correctness and absence of deadlock (and failure) of communicating sequential processes. The key (meta) rule introduces cooperation between proofs, a new concept needed to deal with proofs about synchronization by message passing. CSP's new convention for distributed termination of loops is dealt with. Applications of the method involve correctness proofs for two algorithms, one for distributed partitioning of sets, the other for distributed computation of the greatest common divisor of n numbers.

Keywords and phrases: Hoare-style proof rules, partial correctness, global invariant, cooperating proofs, CSP, communicating processes, concurrency, absence of deadlock, blocking.

1. INTRODUCTION AND PRELIMINARIES

1.1 Introduction

This paper presents a proof system for CSP, a language for Communicating Sequential Processes due to Hoare [11]. This system deals with proofs of partial correctness and of deadlock freedom; proofs of soundness and relative completeness will be published separately by the first author.

Just as CSP sheds new light on the way synchronization and message passing can be employed in a programming language, both by its communication primitives and by the operations upon them, so new insights are needed to obtain a proof system for this language. In particular the following properties of CSP have to be taken care of:

~ CSP stresses simultaneity rather than mutual exclusion as synchronization mechanism by using simultaneous communication as the only means of synchronization.

~ The two communication primitives of CSP, input and output commands, can function as choice mechanism by acting as guards in (possibly nondeterministic) guarded choices and repetitions.

~ CSP focusses on terminating concurrent computations by introducing a distributed termination convention for input/output guarded repetitions.

Correspondingly, to deal with these properties, we introduce:

~ A (meta) rule to establish joint cooperation between isolated proofs for CSP’s sequential components.

In these separate proofs each statement is preceded and followed by a pre- and post-assertion referring only to variables of the process in which the statement appears. These assertions satisfy the axioms and proof rules introduced for the purely sequential constructs of CSP. However, when viewed in the isolation of its sequential component, the post-assertion of an input command cannot be validated since the assertions of its corresponding output command occur in another sequential component. Such proofs cooperate if, taken together, they validate the assertions of the i/o commands mentioned in the isolated proofs. A global invariant is needed to determine which pairs of input and output commands correspond, i.e., are synchronized during execution.
A simple mechanism for expressing termination of repetitive commands, generalizing the expression of the termination criterion "negation of all the boolean guards" to distributed termination of CSP processes. This termination criterion is needed for proof of absence of deadlock and failure; it generalizes the notion of blocking [18] to an environment in which some processes, which are intended to terminate, fail to communicate.

The distinction between cooperation versus combat acted as an almost philosophical guideline in our efforts. Cooperation via resources versus mutual exclusion of critical regions; synchronized communication by means of CSP's communication primitives between a specified pair of processes versus asynchronous interaction by means of shared variables; even purely local variables versus globally shared variables. All these are opposing notions taken from the area of concurrent languages which accentuate in proof theory the problem of finding the missing concept needed to deal with synchronization by message passing: cooperation between proofs. These remarks are elaborated in the last section.

This proof system derives from various related work:

~ Owicki's and Lamport's landmark in the proof theory of concurrent processes [17, 18, 13]. We benefitted also from relative completeness proofs due to Owicki and to Mazurkiewicz [15,16].

~ A still enduring effort spearheaded by Hoare to establish a firm semantic basis for CSP, in which the second and third authors participated, resulting in a denotational semantics [7]. In a later stage this semantics was simplified using a generalization of Dijkstra's weakest precondition operator as a descriptive tool to obtain a characterization of the semantics of terminating programs in CSP [3], which brought the semantics closer to a proof system.

~ The concept of assumption/commitment pairs (interface predicates) as introduced by Francez & Pnueli [8] to characterize the assumptions which a process has to make about the behaviour of its concurrently computing environment in order to enable it "to function properly", so as to justify in its turn the claims made by that environment upon its behaviour; thus, assumption/commitment pairs are assertions which express the cooperation between a process and its environment.
While writing up this paper we learned about related work by Carl Hauser (in preparation) and Chandy & Misra [4]. Sometime after submission of the paper we were informed of independent, very much related, work by G.M. Levin [14] briefly discussed in the last section.

This paper is organized as follows:
Section 1.2 contains a definition of the kernel of CSP with which we deal in this paper. The fragment incorporates guards consisting of pairs of a boolean expression and an input/output command, and also allows nesting of parallelism. Section 2 contains the proof system and is the heart of the paper. Section 3 contains two detailed case studies of correctness proofs — the one of a distributed partition algorithm due to W. Feijen and described in Dijkstra [5] (our proof differs from that of Dijkstra), and the second of an algorithm for the distributed computation of the greatest common divisor of n natural numbers taken from Francez and Rodeh [9]. Section 4 generalizes the proof system to freedom of deadlock and failure, and contains some applications. The last section contains an assessment and comparison of our method with related Hoare-like proof systems for other concurrent languages.

ACKNOWLEDGEMENT: We express our gratitude to Leslie Lamport for his lucid comments on which a substantial part of section 5 is based. We also thank David Luckham, Susan Owicki and Gordon Plotkin for their remarks. Finally, we feel both personally and scientifically indebted to Edsger Dijkstra and Tony Hoare.

1.2. Preliminaries: definition of CSP

Full details of CSP are contained in [11]. For our purpose the following informal description of its syntax and meaning suffices:

~ The basic command of CSP is \([P_1 || \ldots || P_n]\) expressing concurrent execution of processes \(P_1, \ldots, P_n\), \(n \geq 2\).

~ Every \(P_i\) refers to a statement \(S_i\), as indicated by \(P_i :: S_i\). No \(S_i\) contains variables subject to change in \(S_j(i \neq j)\).

~ Communication between \(P_i\) and \(P_j\) \((i \neq j)\) is expressed by the receive and send primitives \(P_j ?x\) and \(P_i !x\), respectively.

Input command \(P_j ?x\) (in \(S_j\)) expresses a request to \(P_j\) to assign a value to the (local) variable \(x\) of \(P_i\).

Output command \(P_i !y\) (in \(S_j\)) expresses a request to \(P_i\) to receive a value from \(P_j\).

Execution of \(P_j ?x\) in \(S_j\) and \(P_i !y\) in \(S_j\) is synchronized (''\(P_i\) waits at \(P_j ?x\) until \(P_j\) is ready at \(P_i !y\) and vice versa'' as the lingo goes) and results in assigning the value of \(y\) to \(x\).
~ Guarded commands: First the case of two guarded possibilities is considered. Let guards \( B_i \) denote boolean expressions, \( i = 1,2 \).

Guarded selection: \([B_1 \rightarrow S_1 \sqcup B_2 \rightarrow S_2]\) fails for \( B_1 \vee B_2 = \text{false} \), and leads to, possibly nondeterministic, selection of \( S_i \) for execution if \( B_i = \text{true} \).

Guarded iteration: \(*[B_1 \rightarrow S_1 \sqcup B_2 \rightarrow S_2]*\) terminates for \( B_1 \vee B_2 = \text{false} \), and otherwise, executes \([B_1 \rightarrow S_1 \sqcup B_2 \rightarrow S_2]; *[B_1 \rightarrow S_1 \circ B_2 \rightarrow S_2]*\).

Now CSP's main feature is that \( P_j ?x \) and \( P_i !y \) can also be used as guards:

As expression, \( P_j ?x \) (respectively \( P_i !y \)) evaluates to \text{false} in case \( P_j \) (respectively \( P_i \)) has terminated.

E.g.,

\[ P_1 :: [P_2 ?x \rightarrow \text{skip} \sqcup P_2 !x \rightarrow \text{skip}] \parallel P_2 :: \text{skip} \]

leads to failure of \( P_1 \).

\[ P_1 :: *[P_2 ?x \rightarrow \text{skip} \sqcup P_2 !x \rightarrow \text{skip}] \parallel P_2 :: \text{skip} \]

properly terminates.

And as expression, \( P_j ?x \) (respectively \( P_i !y \)) evaluates to \text{true} if synchronization occurs with a matching output (respectively input) command or guard.

E.g.,

\[ P_1 :: [P_2 ?x \rightarrow \text{skip} \sqcup P_2 !x \rightarrow \text{skip}] \parallel P_2 :: [P_1 ?y \rightarrow \text{skip} \sqcup P_1 !y \rightarrow \text{skip}] \]

has the same effect as executing \( x := y \) or \( y := x \) nondeterministically, and

\[ P_1 :: *[P_2 ?x \rightarrow \text{skip}] \parallel P_2 :: P_1 !0 \]

has the same effect as executing \( x := 0 \) just once.

In Hoare's conception of CSP only finite processes are considered; thus

\[ P_1 :: *[P_2 ?x \rightarrow \text{skip}] \parallel P_2 :: *[P_1 !0 \rightarrow \text{skip}] \]

so called infinite chattering, is considered as a semantic error.

~ "\( \sqcup \)" denotes the guard separator. Guards may be boolean (\( b_i \)'s) passable when true, or i/o commands passable when a corresponding i/o command in this process addressed is ready, or a combination of both, passable when its boolean part is true and the process addressed is ready.

~ A guarded selection fails in case all its guards are false.
A guard is false in one of the following cases:
  i) it is a boolean expression evaluating to false;
  ii) it is an i/o command for which the process addressed
      has terminated;
  iii) it is a combination of a boolean expression and an i/o command
      and either the boolean expression is false, or the process
      addressed in the i/o command has terminated.

~ "*" denotes a repetitive construct. Repetition continues as long
as there exists a passable guard, and terminates when all guards
are false.

~ ";" denotes sequential composition.

~ "skip" is a statement with no effect.

~ Nested parallelism requires the following refinements: the scope
of a process name extends to the whole of the parallel command.
No process can be named outside its scope. This implies that
within the following program \([P_1 \parallel [P_{11} \parallel P_{12} \parallel S_1] \parallel P_{2} \parallel S_2] S_2\)
can only contain references to \(P_1\), whereas both \(P_{11}\) and \(P_{12}\) may
address \(P_2\), e.g.,

\[
\begin{align*}
P_{11} &:: P_{12}'x, \\
P_{12} &:: P_{11}'y; P_2'y, \\
P_2 &:: P_1'u.
\end{align*}
\]

To avoid problems arising from local variable declarations, we assume
that nesting of parallelism introduces no name clashes (of both
variable and process names).

Guarded commands (i.e., selection or repetition) introduce the possibility
that more than one matching pair of i/o commands occurs; e.g., in the example
below the first communication of \(P_1\) can be either with \(P_2\) or with \(P_3\), but not
simultaneously with both: \(P :: [P_1 \parallel P_2 \parallel P_3]\), where:

\[
\begin{align*}
P_1 &:: [P_2'x \rightarrow S_1 \oplus b_1, P_3'y \rightarrow S_2]; \\
     &*[b_2', P_2'u \rightarrow S_3 \oplus b_3, P_3'u \rightarrow S_4] \\
P_2 &:: *[P_1's \rightarrow S_5 \oplus P_1't \rightarrow S_6 \oplus P_3's \rightarrow S_7] \\
P_3 &:: P_1'z; *[b_1 \rightarrow S_8 \oplus b_2 \rightarrow S_9].
\end{align*}
\]

Finally, to avoid some cumbersome notational problems in section 4,
we consider in this paper only guarded commands of which all the guards either
contain all an i/o command, or are all boolean.
2. THE PROOF SYSTEM

We intend to reason about CSP programs in a manner analogous to the work of Owicki and Gries [18]: first we present proofs for processes in separation and then we deduce properties of complete programs by comparing the proofs for the component processes. Therefore, we have to provide axioms and proof rules for all possible constructs of a process. One of the essential properties of CSP programs is that the meaning of processes viewed in isolation is inherently incomplete when compared with their meaning in the context of a complete program. This phenomenon is also present in a less obvious way in the case of the language considered in [17] and [18], where the constructs \texttt{await b then S} and \texttt{with r when b do S} are meaningful, essentially, only in the context of parallel composition. Therefore, the axioms and proof rules dealing with the constructs pertinent to CSP do not capture a complete meaning of these constructs viewed separately.
The main novel contribution of this work is in our opinion the proposal of tying separate proofs together into a meaningful whole; this proposal, the test for cooperation between proofs, will be discussed shortly.

We adopt the following axioms and proof rules ($a_i$ stand for i/o commands):

A1. input

\[
(p) \text{ P}_i ? x \{ q \}
\]

This axiom may look strange since it allows to deduce any post-assertion $q$ of the input command whatsoever. However, any $q$ thus introduced will be later (when proofs are tested for cooperation) checked against some post-assertion regarding corresponding output statements. An arbitrary $q$ will in general fail to pass the cooperation test.

A2. output

\[
(p) \text{ P}_i ! y \{ p \}
\]

This axiom conveys the information that an output statement has no side effect.

R1. i/o guarded selection

\[
\frac{(p) \{ \text{[]} (i = 1, \ldots, m) b_i, a_i \rightarrow s_i \} \{ q \} \quad \{ p \wedge b_i \} a_i \{ r_i \}, \{ r_i \} s_i \{ q \}, \quad i = 1, \ldots, m}{\{ p \} \{ \text{[]} (i = 1, \ldots, m) b_i, a_i \rightarrow s_i \} \{ q \}}
\]

The meaning of this rule is that the post-assertion of an i/o guarded selection must be established along each possibly selected path. We discuss later the problem of paths never selected.

R2. i/o guarded repetition

\[
\frac{(p) \{ \text{[]} (i = 1, \ldots, m) b_i, a_i \rightarrow s_i \} \{ p \} \quad \{ p \wedge b_i \} a_i \{ r_i \}, \{ r_i \} s_i \{ p \}, \quad i = 1, \ldots, m}{\{ p \} \{ \text{[]} (i = 1, \ldots, m) b_i, a_i \rightarrow s_i \} \{ p \}}
\]

Note that this rule does not take into account the full exit conditions of the loop. We shall return to this problem at the end of the section.

Subsequently we use the following well known axioms and proof rules:

A3. assignment

\[
(p \ [t/x]) \ x = t \{ p \}
\]

A4. skip

\[
(p) \ \text{skip} \{ p \}
\]

R3. alternative command

\[
\frac{(p) \{ \text{[]} (i = 1, \ldots, m) b_i \rightarrow s_i \} \{ q \} \quad \{ p \wedge b_i \} s_i \{ q \}}{\{ p \} \{ \text{[]} (i = 1, \ldots, m) b_i \rightarrow s_i \} \{ q \}}
\]

R4. repetitive command

\[
\frac{(p) \{ \text{[]} (i = 1, \ldots, m) b_i \rightarrow s_i \} \{ p \wedge \neg (b_1 \lor \ldots \lor b_m) \}}{\{ p \} \{ \text{[]} (i = 1, \ldots, m) b_i \rightarrow s_i \} \{ p \wedge \neg (b_1 \lor \ldots \lor b_m) \}}
\]
R5. **composition**

\[
\begin{align*}
(p) & \quad S_1 \{q\}, \quad [q] \quad S_2 \{r\} \\
(p) & \quad S_1; \quad S_2 \{r\}
\end{align*}
\]

R6. **consequence**

\[
\begin{align*}
p & \rightarrow p_1, \quad [p_1] \quad S\{q_1\}, \quad q_1 \rightarrow q \\
(p) & \quad S\{q\}
\end{align*}
\]

R7. **conjunction**

\[
\begin{align*}
(p) & \quad S\{q\}, \quad (p) \quad S\{r\} \\
(p) & \quad S\{q \land r\}
\end{align*}
\]

Using these axioms and proof rules we can establish proofs for formulae of the form \(p) \quad P_i \{q\}\) where \(P_i\) is a process. Each such proof can be represented, as in \([18]\), by a **proof outline** in which each substatement \(S\) of \(P_i\) is preceded and followed by a corresponding assertion, \(\text{pre}(S)\) and \(\text{post}(S)\), respectively. The subsequent discussion will always refer to proofs presented in such a form.

We now present a first formulation of a proof rule (or rather a metarule) which can be used to deduce a property of \([P_1 \parallel \ldots \parallel P_n]\) using the proofs concerning programs \(P_i\), \(i = 1, \ldots, n\). This rule has the following form:

\[
\begin{align*}
\text{proofs on } (p_i) \quad P_i \{q_i\} & \quad i = 1, \ldots, n, \text{ cooperate} \\
(p_1 \land \ldots \land p_n) \quad [P_1 \parallel \ldots \parallel P_n] \quad \{q_1 \land \ldots \land q_n\}
\end{align*}
\]

Intuitively, proofs cooperate if they help each other to validate the post-assertions of the i/o statements mentioned in those proofs. More formally this property is expressed, as follows:

The proofs of \((p_i) \quad P_i \{q_i\} \quad i = 1, \ldots, n, \text{ cooperate if:}\)

i) The assertions used in the proof of \((p_i) \quad P_i \{q_i\}\) contain no variables subject to change in \(P_j\) for \(i \neq j\);

ii) \((\text{pre}_1 \land \text{pre}_2) \quad P_i ?x \parallel P_j ?y \quad \{\text{post}_1 \land \text{post}_2\}\) holds whenever \((\text{pre}_1) \quad P_i ?x \quad \{\text{post}_1\}\) and \((\text{pre}_2) \quad P_j ?y \quad \{\text{post}_2\}\) are taken from the proofs of \((p_i) \quad P_i \{q_i\}\) and \((p_j) \quad P_j \{q_j\}\), respectively.*

We shall need the following axioms to establish cooperation:

A5. **communication**

\[
\text{true} \quad P_i ?x \parallel P_j ?y \quad \{x = y\}
\]

provided \(P_i ?x\) and \(P_j ?y\) are taken from \(P_j\) and \(P_i\), respectively.

A6. **preservation**

\[
(p) \quad S\{p\}
\]

provided no free variable of \(p\) is subject to change in \(S\).

* Such pairs of i/o instructions will be said to be **syntactically matching**.
Note that A2 and A4 are subsumed by A6. We shall also need the following proof rule, needed to eliminate auxiliary variables from the pre-assertions.

**R8. substitution**

\[
\begin{align*}
\{p\} S \{q\} \\
\hline
\{p [t/z]\} S \{q\}
\end{align*}
\]

provided \(z\) does not appear free in \(S\) and \(q\).

**Example 1.** Using the system above we can prove

\[
\{\text{true}\}[P_1 \parallel P_2 \parallel P_3] \{x = u\},
\]

where \(P_1 \equiv P_2 !x,\)

\(P_2 \equiv P_1 ?y; P_3 !y,\)

\(P_3 \equiv P_2 ?u.\)

Here are the proof outlines:

\[
\{x = z\} P_2 !x \{x = z\},
\]

\[
\{\text{true}\} P_1 ?y \{y = z\}; P_3 !y \{y = z\},
\]

\[
\{\text{true}\} P_2 ?u \{u = z\}.
\]

The proofs clearly cooperate – for example,

\[
\{x = z\} P_2 !x \parallel P_1 ?y \{x = z \land y = z\} \text{ can be derived as follows.}
\]

By the communication axiom \(\{\text{true}\} P_2 !x \parallel P_1 ?y \{x = y\},\) so by the consequence rule \(\{x = z\} P_2 !x \parallel P_1 ?y \{x = y\}.\) On the other hand by the preservation axiom \(\{x = z\} P_2 !x \parallel P_1 ?y \{x = z\}\) so by the conjunction rule \(\{x = z\} P_2 !x \parallel P_1 ?y \{x = y \land x = z\}.\)

Finally \(\{x = z\} P_2 !x \parallel P_1 ?y \{x = z \land y = z\}\) by the consequence rule.

Thus we get \(\{x = z\} [P_1 \parallel P_2 \parallel P_3] \{x = z \land y = z \land u = z\}.\) Now by applying the consequence rule we get \(\{x = z\} [P_1 \parallel P_2 \parallel P_3] \{x = u\} \) from which the claim follows by applying the substitution rule, and substituting \(x\) for \(z\) in the precondition.

\[\square\]

This approach fails when dealing with programs in which some output commands do not match with any input command.

**Example 2.** Let

\[
\begin{align*}
P_1 & \equiv P_2 !0, \\
P_2 & \equiv [P_1 ?x \rightarrow \text{skip}] P_3 !y \rightarrow \text{skip} \parallel P_3 ?y \rightarrow \text{skip}, \\
P_3 & \equiv \text{skip}.
\end{align*}
\]

Clearly, \(\{\text{true}\} [P_1 \parallel P_2 \parallel P_3] \{x = 0\}\) holds. However this cannot be proved in the above system, for any such proof would require to establish both \(\{\text{true}\} P_3 !y \{x = 0\}\) and \(\{\text{true}\} P_3 ?y \{x = 0\}\). The latter formula is an instance of the input axiom but the former one cannot be derived in the system. \[\square\]
We remedy this difficulty by introducing the following, rather astonishing, new output axiom:

\[
\{p\} P_1^1 : y \{q\}
\]

At this moment the reader might wonder: "Does not the combination of axioms A1 and A2', i.e., of \(\{p\} P_1^1 x \{q\}\) and \(\{p\} P_j^j y \{q\}\) together allow us to deduce \(\{p\} P_1^1 x \parallel P_j^j y \{q\}\) for arbitrary p and q?" That this is not the case follows from the cooperation test. Using A5, the axiom of communication, and A6, the axiom of preservation, only formulae of the form \(\{r\} P_1^1 x \parallel P_j^j y \{x = y \land r\}\) can be derived, where x is not free in r, and any use of the substitution or consequence rule can only weaken the conclusion.

We hope that these remarks indicate to what extent the choice of p and q above is restricted by requiring cooperation.

Next we solve the following problem:

The cooperation test between proofs requires to compare all i/o pairs which syntactically match, even though some syntactically possible communications will never take place. A simple example follows where we run into difficulties because of this very reason:

**Example 3.** Let

\[
P_1 :: [P_2^2 x \rightarrow \text{skip} \parallel P_2^2 !0 \rightarrow P_2^2 x; \ x := x + 1],
\]

\[
P_2 :: [P_1^1 ?2 \rightarrow \text{skip} \parallel P_1^1 ?z \rightarrow P_1^1 !1].
\]

Clearly, \(\{\text{true}\} [P_1 \parallel P_2] \{x = 2\}\) holds. To prove this we are forced to use \(x = 2\) as the post-assertion of the first occurrence of \(P_2^2 x\) in \(P_1\). This assertion, however, will not pass the test for cooperation since it cannot be validated when \(P_2^2 x\) is compared with \(P_1^1 !1\) (; the point being that this pair also syntactically matches, although it will not be synchronized during execution).

\[\Box\]

In general, syntactic matching of a pair of i/o instructions does not imply yet that this communication will ever take place, i.e., imply their semantic match. In order to take care that semantically not matching pairs of i/o instructions do not fail the cooperation test as above, we introduce a global invariant I which will determine semantic matches, and which may carry other global information needed for the proof. However, in order to express semantic matching in general one needs variables which are not necessarily the ones referred to in the i/o instructions themselves (and, as is well known, needn't be program variables either; in general auxiliary variables are needed).

For example, consider the following program sections:

\[
... \ P_2^2 x; \ i := i + 1 \ ... \parallel \ ... \ P_1^1 y; \ j := j + 1 \ ...
\]
where $i$ and $j$ count the number of communications actually occurring in each process, and let therefore the criterion for semantic matching be $i = j$. However, $i = j$ is no global invariant since the two assignments to $i$ and $j$ will not necessarily be executed simultaneously, in contrast to the corresponding i/o commands which are executed simultaneously.

To resolve these difficulties we must reduce the number of places where the global invariant should hold. This will be done by introducing brackets, the purpose of which is to delimit program sections within which the invariant need not necessarily hold.

This phenomenon is similar to the one concerning resource invariants of Hoare (see [10]) where the global invariant does not need to hold within the critical sections. An analogous problem arises when dealing with monitor invariants (see [12]).

Regarding the program sections just considered the bracketing will be

$$... \langle P_2 \exists x; i := i + 1 \rangle ... \parallel ... \langle P_1 \forall y; j := j + 1 \rangle ...$$

so that $i = j$ will hold outside the brackets.

Definition: A process $P_i$ is bracketed if the brackets "\" and "\" are interspersed in its text, so that for each program section $\langle S \rangle$ (to be called a bracketed section), $S$ is of one of the following forms:

i) $S_1; \alpha; S_2$

or

ii) $\alpha \rightarrow S_1$,

and $S_1$ and $S_2$ do not contain any i/o statements.

\[\Box\]

With each proof of $\{p\} [P_1 \parallel ... \parallel P_n] \{q\}$ we now associate a global invariant $I$, and appropriate brackets. Therefore the proof rule concerning parallel composition becomes as follows (in second approximation):

R9. **parallel composition**

\[
\text{proofs of }\{p_i\} P_i \{q_i\}, i = 1, ..., n \text{ cooperate} \quad \frac{\text{prove} \quad \{p_1 \land ... \land p_n \land I\} [P_1 \parallel ... \parallel P_n] \{q_1 \land ... \land q_n \land I\} \text{ provided} \\
\text{no variable free in } I \text{ is subject to change outside} \\
a \text{ bracketed section.} \\
\text{We have now to define precisely when proofs cooperate. Assume a given} \\
\text{ bracketing of } [P_1 \parallel ... \parallel P_n] \text{ (to which we referred in the clause concerning the free variables of } I).
**Definition.** Let $<S_1>$ and $<S_2>$ denote two bracketed sections from $P_i$ and $P_j$ ($i \neq j$). We say that $<S_1>$ and $<S_2>$ match if $S_1$ and $S_2$ contain matching i/o commands.

**Definition.** The proofs of the $\{p_1\} P_i \{q_i\}, i = 1, ..., n,$ cooperate if

(i) the assertions used in the proof of $\{p_1\} P_i \{q_i\}$ have no free variables subject to change in $P_j$ ($i \neq j$).

(ii) $(\mathsf{pre}(S_1) \land \mathsf{pre}(S_2) \land I) S_1 \parallel S_2 (\mathsf{post}(S_1) \land \mathsf{post}(S_2) \land I)$ holds for all matching pairs of bracketed sections $<S_1>$ and $<S_2>$.

The following additional proof rules are used to establish cooperation:

**R10. formation**

$$\frac{\{p\} S_1; S_3 \{p_1\}, \{p_1\} \alpha \parallel \bar{\alpha} \{p_2\}, \{p_2\} S_2; S_4 \{q\}}{\{p\} (S_1; \alpha; S_2) \parallel (S_3; \bar{\alpha}; S_4) \{q\}}$$

provided $\alpha$ and $\bar{\alpha}$ match, and $S_1$, $S_2$, $S_3$, $S_4$ do not contain any i/o commands.

**R11. arrow**

$$\frac{\{p\} (\alpha; S) \parallel S_1 \{q\}}{\{p\} (\alpha \rightarrow S) \parallel S_1 \{q\}}$$

R10 and R11 reduce the proof of cooperation to sequential reasoning, except for an appeal to the communication axiom. In this sequential reasoning, assertions appearing within brackets can be used.

Finally, we use auxiliary variables whenever needed. These are variables which do not affect program control during execution, and are added only for expressing assertions and invariants, which cannot be expressed in terms of the program variables alone. We use rule R12, a slightly strengthened version of a rule from [18] for deleting assignments to auxiliary variables.

**R12. auxiliary variables**

Let $AV$ be a set of variables such that $x \in AV \Rightarrow x$ appears in $S'$ only in assignments $y := t$, where $y \in AV$. Then if $q$ does not contain free any variables from $AV$, and $S$ is obtained from $S'$ by deleting all assignments to variables in $AV$,

$$\frac{\{p\} S' \{q\}}{\{p\} S \{q\}}$$
Example 4. We now show how to verify the program from example 3. Two auxiliary variables $i$ and $j$ are needed. We give proof outlines for the already bracketed program $S$.

\[
\begin{align*}
{i = 0 \land j = 0} \\
[\{i = 0\}] \\
\langle P_2 \forall x \{x = 2\} \rightarrow i := 1 > \{x = 2 \land i = 1\}; \text{skip} \{x = 2\} \\
\top \\
\langle P_2 \forall 0 \{\text{true}\} \rightarrow i := 1 > \{i = 1\}; \langle P_2 \forall x \{x = 1\}; \\
i := 2 > \{x = 1 \land i = 2\}; x := x + 1 \{x = 2\} \\
\top \{x = 2\} \\
\|$ \\
[\{j = 0\}] \\
\langle P_1 \forall 12 \{\text{true}\} \rightarrow j := 1 > \{j = 1\}; \text{skip} \{\text{true}\} \\
\top \\
\langle P_1 \forall z \{z = 0\} \rightarrow j := 1 > \{z = 0 \land j = 1\}; \langle P_1 \forall !1 \{\text{true}\}; \\
j := 2 > \{j = 2\} \\
\top \{\text{true}\} \\
\} \{x = 2\}
\end{align*}
\]

We choose $I = \{i = j\}$. Cooperation is easily established. Note that $(i = 0 \land (z = 0 \land j = 1) \land I) = \text{false}$, so the bracketed sections containing $P_2 \forall x$ and $P_1 \forall !1$ pass the cooperation test trivially. (One has for any $S, \{\text{false}\} S \{\text{false}\}$ by the preservation axiom, so $\{\text{false}\} S \{p\}$ for any $p$ by the consequence rule.) Hence by the parallel composition rule, consequence rule and rule R12,

\[
\{i = 0 \land j = 0 \land i = j\} [P_1 || P_2] \{x = 2\}
\]

holds. Applying the substitution rule we finally get

\[
\{\text{true}\} [P_1 || P_2] \{x = 2\}
\]

\[
\square
\]

The last example we deal with concerns nested parallelism.

Example 5. Consider

\[
[P_1 :: [P_{11} || P_{12}] || P_2],
\]

where

\[
P_{11} :: P_{12} !x,
P_{12} :: P_{11} ?y; P_2 !y,
P_2 :: P_1 ?u.
\]
We wish to prove, similarly as in Example 1, that
\{true\} [P_1 \parallel P_2] \{x = u\} holds.
First we give proof outlines for P_{11} and P_{12}:

\begin{align*}
P_{11} &:: (x = z) \ P_{12} : x \ {x = z}, \\
P_{12} &:: (true) \ P_{11} \ ?y \ {y = z}; \ P_2 \ !y \ {y = z}.
\end{align*}
These proof outlines obviously cooperate (observe that the output command P_2 !y has no matching input command).

Next we give proof outlines for P_1 and P_2:

\begin{align*}
P_1 &:: (x = z) \ [P_{11} :: (x = z) \ P_{12} : x \ {x = z}] \\
&\parallel \\
P_{12} &:: (true) \ P_{11} \ ?y \ {y = z}; \ P_2 \ !y \ {y = z}] \\
&\quad (x = z \land y = z), \\
&P_2 :: (true) \ P_1 \ ?u \ {u = z}.
\end{align*}
Note that the proof outline for P_1 incorporates proof outlines for
P_{11} and P_{12}; since these cooperate they justify the use of the parallel composition rule. In this way we generalize the notion of proof outline
to cover nested parallelism.

Now, at the next level, we consider the proof outlines for P_1 and P_2.
They cooperate - the only matching pair consists of P_2 !y and P_1 ?u, so
by the rule of parallel composition we get
\{ (x = z) [P_1 \parallel P_2] \ {x = z \land y = z \land u = z}. 
The rest of the proof is the same as in Example 1. This suggests
that no problems arise when applying our proof system to programs
containing nested parallelism.

\[\square\]

At this stage we return to the problem signalled earlier - namely that
of rule R2. Rule R2 alone does not provide any means to deduce that upon exit
of the loop \(*[i = 1, \ldots, m] *b_i, a_i \rightarrow S_i]\ some of b_i 's may be false. Now, that
we introduce global invariants, we can settle this problem by expressing exit
conditions in the global invariant I. As an illustration, let us prove
\begin{align*}
&\{ ; \ P_1 \parallel P_2 \} \{b\} with \\
&P_1 :: \ *[b, \ P_2 ?x \rightarrow b := false] \\
\text{and} \\
P_2 :: \ \text{skip}.
\end{align*}
We simply choose I to be b and take all other assertions true. The cooperation of proofs is voidly satisfied.

A slightly less trivial proof establishes \( \text{true} \) \( [P_1 \parallel P_2](\neg b) \) with \( P_1 \) as above and \( P_2 :: P_1!y \). In this case we have to express the fact that after the communication takes place \( b \) turns false. To this purpose we introduce an auxiliary variable \( i \).

We present the proof outlines for the bracketed programs
\[
\{\text{true}\} * [b, \langle P_2 ? x \rightarrow b:= \text{false} \rangle] \{\text{true}\}
\]
\[
\{i = 0\} \langle P_1 ! y; i:= 1 \rangle \{i = 1\}.
\]

We choose for I the formula \( i = 1 \rightarrow \neg b \). Cooperation is easily established using the formation rule. By the parallel composition rule, consequence rule and rule R12
\[
\{i = 0 \wedge (i = 1 \rightarrow \neg b)\} [P_1 \parallel P_2](\neg b),
\]
so finally by the substitution rule \( \text{true} \) \( [P_1 \parallel P_2](\neg b) \).

These two examples were given to indicate why rule R2 is sufficient for proofs of partial correctness. In section 4 we shall discuss the problem whether this rules is sufficient for proofs of deadlock freedom.

3. CASE STUDIES

3.1 Partitioning a set

Given two disjoint sets of integers \( S \) and \( T; S \cup T \) has to be partitioned into two subsets \( S' \) and \( T' \) s.t. \( |S| = |S'|, |T| = |T'| \), and every element of \( S' \) is smaller than any element of \( T' \). The program \( P \) and its correctness proof are inspired upon Dijkstra [5]; however the proof presented here differs from Dijkstra's one. \( P :: [P_1 \parallel P_2] \), as given below, and \( S \neq \emptyset \).

\[
P_1 :: \begin{align*}
& \text{mx} := \text{max}(S); \\
& P_2 ! mx; \ S := S - \{mx\}; \\
& P_2 ? x; \ S := S \cup \{x\}; \\
& \text{mx} := \text{max}(S)
\end{align*}
\]

\[
P_2 :: \begin{align*}
& P_1 ? y; \ T := T U \{y\}; \\
& \text{mn} := \text{min}(T); \\
& P_1 ! mn; \ T := T - \{mn\}; \\
& P_2 ? x; \ S := S \cup \{x\}; \\
& \text{mn} := \text{min}(T); \\
& \text{mx} := \text{max}(S)
\end{align*}
\]

Intuitively, these programs execute the following loop: Let \( S \) and \( T \) denote set variables; then processes \( P_1 \) and \( P_2 \) exchange the current maximum of \( S, \text{max}(S) \), with the current minimum of \( T, \text{min}(T) \), until \( \text{max}(S) \) in \( P_1 \) equals the value last received from \( P_2 \).
The correctness proof of P requires the introduction of two auxiliary variables $k_1$ in P_1 and $k_2$ in P_2, to enable expression of the global invariant GI; $k_1$ counts the number of communications performed by P_1.

The purposes of GI are:
1) to determine which syntactically matching bracketed sections are executed indeed (by requiring $k_1 = k_2$);
2) to guarantee the partitioning property;
3) to tie the local reasoning required for processes P_1 and P_2 in isolation together so as to permit derivation of max (S) ≥ min (T) upon (joint) loop exit; to express the global conditions on S and T needed for the local reasoning about P_1 and P_2 (in testing for cooperation).

In the annotated versions of P_1 and P_2, P'_1 and P'_2, the following is added to their "bare" text:
1) Assignments to the auxiliary variables $k_1$, $k_2$.
2) The pre- and post-conditions required for a proof, modulo deletions of conditions which were mentioned earlier in the annotated text and remained invariant, or were not relevant at earlier points.
3) Bracketed sections of instructions which, from the point of view of the proof, are considered as units for the proof of cooperation. Note that the global invariant GI requires $S \cap T = \emptyset$, and that $S := S - \{mn\}$ and $T := T \cup \{y\}$ are not synchronized. Thus within these units GI may be violated indeed, but not outside these units.

Annotated text of P_1:

\[
\begin{align*}
\{&|S| = n_1 \geq 0 \land S = S_0 \land \max (S) \in S \land k_1 = 0\} \quad \text{mx} := \max (S); \\
&|S| = n_1 \land k_1 = 0 \\
\text{< P}_2 \text{!mx}; \quad k_1 := k_1 + 1; \quad \text{mx} \in S \} \\
&\{|S| = n_1 - 1 \land k_1 = 1\} \\
\text{< P}_2 \text{?x}; \quad k_1 := k_1 + 1; \quad \{x \notin S\} \\&\{S := S \cup \{x\}\} >; \\
&\{|S| = n_1 \land x \in S \land k_1 = 2\}
\end{align*}
\]

LI_1: \(|S| = n_1 \land \text{mx} = \max (S) \land x \leq \max (S) \land \text{even} (k_1) \land k_1 \geq 2\) \[
\begin{align*}
&\{\text{mx} \geq x \rightarrow \{\text{mx} \in S \land LI_1\} \land \text{< P}_2 \text{!mx}; \quad k_1 := k_1 + 1; \quad \{\text{mx} \in S\} \\
&\quad S := S - \{\text{mx}\}\} >; \\
&\{|S| = n_1 - 1 \land \text{odd} (k_1) \land k_1 \geq 2\} \\
&\text{< P}_2 \text{?x}; \quad k_1 := k_1 + 1; \quad \{x \notin S\}; \quad S := S \cup \{x\} >; \\
&\{|S| = n_1 \land x \in S \land \text{even} (k_1)\} \\
&\quad \text{mx} := \max (S) \\
&\quad LI_1: \{|S| = n_1 \land x \in S \land \text{mx} = \max (S) \land \text{even} (k_1) \land k_1 \geq 2\} \\
\end{align*}
\]

\[
\{\max (S) = x \land |S| = n_1 \land \text{even} (k_1)\}
\]
Annotated text of $P_2$:

\[
\begin{align*}
|T| &= n_2 \geq 0 \land T = T_0 \land \ell_2 = 0 \\
&< P_1 y; \ell_2 := \ell_2 + 1; \{y \notin T\} T := T \cup \{y\} >; \\
|T| &= n_2 + 1 \land \ell_2 = 1 \land mn := \min(T); \\
|T| &= n_2 + 1 \land mn = \min(T) \land \ell_2 = 1 \\
&< P_1 !mn; \ell_2 := \ell_2 + 1; \{mn \in T\} T := T - \{mn\} >; \\
\text{LI}_2: \{|T| = n_2 \land mn < \min(T) \land \text{even} (\ell_2) \land \ell_2 \geq 2\} \\
&*[< P_1 y \rightarrow \ell_2 := \ell_2 + 1; T := T \cup \{y\} >; \\
|T| &= n_2 + 1 \land \text{odd} (\ell_2) \land mn := \min(T); \\
&< P_1 !mn; \ell_2 := \ell_2 + 1; T := T - \{mn\} >; \\
\text{LI}_2: \{|T| = n_2 \land mn < \min(T) \land \text{even} (\ell_2) \land \ell_2 \geq 2\}
\]

The global invariant GI:

\[
GI = S \cap T = \emptyset \land S \cup T = S_0 \cup T_0 \land \ell_1 = \ell_2 \land \\
\text{even} (\ell_1) \land \ell_1 \geq 2 \Rightarrow x \leq \min(T).
\]

For the sake of the proof we assume that $\min(\emptyset) = + \infty$.

We restrict ourselves to proving cooperation between proofs for the first bracketed section of $P_1$ and of $P_2$, and for the second bracketed section of $P_1$ and $P_2$; the customary kind of sequential reasoning is omitted. Proofs for the cooperation for the third bracketed sections and the fourth ones are actually identical, and omitted. Proofs for syntactically matching but semantically non-matching sections are trivial; e.g., the first section of $P_1$ and the third one of $P_3$ are trivially cooperating since $\neg GI$ holds (in this case $\neg (\ell_1 = 0 \land \ell_2 \geq 2 \land \ell_1 = \ell_2)$). Note also how the input and output axioms are used to insert the occurrences of $\{mx \in S\}$, $\{x \in S\}$, $\{y \in T\}$ and $\{mn \in T\}$ in the annotated program; the choice of these assertions will be justified in the cooperation proofs.

Proof of cooperation between first bracketed sections:

One has $\text{pre}_1 = mx \in S \land |S| = n_1 \land \ell_1 = 0$, and

$\text{pre}_2 = |T| = n_2 \land T = T_0 \land \ell_2 = 0$.

Also, $\text{post}_1 = |S| = n_1 - 1 \land \ell_1 = 1$, $\text{post}_2 = |T| = n_2 + 1 \land \ell_2 = 1$.

We have to prove: $\{\text{pre}_1 \land \text{pre}_2 \land GI\}$

$P_2 : \text{mx}; \ell_1 := \ell_1 + 1; S := S - \{mx\} \parallel P_1 y; \ell_2 := \ell_2 + 1; T := T \cup \{y\}$

$\{\text{post}_1 \land \text{post}_2 \land GI\}$.
By the communication and preservation axioms,
\[
\{\text{pre}_1 \land \text{pre}_2 \land \text{GI}\} \ P_2.?x \parallel P_1.?y \ \{\text{mx} = y \land \text{pre}_1 \land \text{pre}_2 \land \text{GI}\}.
\]
Pre-condition of section \(l_1 := l_1 + 1; S := S \cup \{\text{mx}\}; l_2 := l_2 + 1; T := T \cup \{y\}\) w.r.t. post-condition \(\text{post}_1 \land \text{post}_2 \land \text{GI}\) is
\[
l_1 = l_2 = 0 \land y \notin T \land |T| = n_2 \land \text{mx} \in S \land |S| = n_1 \land S \cap T = \emptyset \land S \cup T = S_0 \cup T_0,
\]
which is implied by \(\{\text{mx} = y \land \text{pre}_1 \land \text{pre}_2 \land \text{GI}\}\).

Therefore the formation rule yields the result since
\[
\{\text{pre}_1 \land \text{pre}_2 \land \text{GI}\} \ P_2.?x \parallel P_1.?y \ \{\text{mx} = y \land \text{pre}_1 \land \text{pre}_2 \land \text{GI}\} \quad \text{and}
\]
\[
\{\text{mx} = y \land \text{pre}_1 \land \text{pre}_2 \land \text{GI}\} \ l_1 := l_1 + 1; S := S \cup \{\text{mx}\}; l_2 := l_2 + 1; T := T \cup \{y\} \quad \{\text{post}_1 \land \text{post}_2 \land \text{GI}\} \text{ holds.}
\]

**Proof of cooperation between second bracketed sections:**

One has \(\text{pre}'_1 = |S| = n_1 - 1 \land l_1 = 1\), and
\[
\text{pre}'_2 = |T| = n_2 + 1 \land mn = \min (T) \land l_2 = 1; \text{ and}
\]
\[
\text{post}'_1 = |S| = n_1 \land x \in S \land l_1 = 2,
\]
\[
\text{post}'_2 = |T| = n_2 \land mn < \min (T) \land \text{even } (l_2) \land l_2 \geq 2.
\]

We have to prove: \(\{\text{pre}'_1 \land \text{pre}'_2 \land \text{GI}\}
\]
\[
P_2.?x; l_1 := l_1 + 1; S := S \cup \{x\} \parallel P_1.?\text{mn}; l_2 := l_2 + 1; T := T \setminus \{\text{mn}\}
\]
\[
\{\text{post}'_1 \land \text{post}'_2 \land \text{GI}\}.
\]

By the communication axiom and preservation axiom
\[
\{\text{pre}'_1 \land \text{pre}'_2 \land \text{GI}\} P_2.?x \parallel P_1.?\text{mn} \ \{\text{mn} = x \land \text{pre}'_1 \land \text{pre}'_2 \land \text{GI}\},
\]
since odd \((l_1)\).

Now observe that
\[
\{\text{mn} = x \land \text{pre}'_1 \land \text{pre}'_2 \land \text{GI}\}
\]
\[
l_1 := l_1 + 1; S := S \cup \{x\}; l_2 := l_2 + 1; T := T \setminus \{\text{mn}\}
\]
\[
\{\text{post}'_1 \land \text{post}'_2 \land \text{GI}\}
\]
holds.

Note that \(x < \min (T)\) in the post-assertion follows from the fact that
\[mn = x \land mn = \min (T) \land x < \min (T \setminus \{\text{mn}\});\]

Therefore the formation rule yields the result.

Applying the rule of parallel composition we get
\[
\{\lceil S \rceil = n_1 > 0 \land S = S_0 \land |T| = n_2 \geq 0 \land T = T_0 \land l_1 = 0 \land l_2 = 0 \land \text{GI}\}
\]
\[
[P'_1 \parallel P'_2]
\]
\[
[L_1^{\parallel} \land L_2^{\parallel} \land \text{GI}]
\]
where \( P'_1 \wedge P'_2 \) are the modified versions of \( P_1 \) and \( P_2 \).

From this we obtain

\[
\begin{align*}
\{ S \mid n_1 > 0 \wedge S = S_0 \wedge |T| = n_2 \geq 0 \wedge T = T_0 \wedge S \cap T = \emptyset \\
\wedge \ell_1 = 0 \wedge \ell_2 = 0 \},
\end{align*}
\]

\[ P'_1 \parallel P'_2 \]

\[
\{ S \mid n_1 \wedge |T| = n_2 \wedge S \cap T = \emptyset \wedge S \cup T = S_0 \cup T_0 \wedge \max(S) < \min(T) \}.
\]

Now by dropping the assignments to \( \ell_1 \) and \( \ell_2 \) and subsequently substituting 0 for \( \ell_1 \) and \( \ell_2 \) in the pre-condition we get the desired formula.

3.2. Distributed computation of the greatest common divisor of \( n \) numbers

As another example, we shall consider a program \( P \) which computes

\[ \gcd(\sigma_1, \ldots, \sigma_n), \sigma_i > 0, i = 1, \ldots, n, \]

a variant of a program first presented in [9]. This program has the property that when all processes reach a final state and have computed the \( \gcd \), the program is blocked in a deadlock state, since no process "knows" that all other processes are in final states. The interest in such programs arises because of two facts:

1. It may be easier to write such a program then the corresponding program that will terminate when all processes reached final states.
2. There exists an automatic transformation transforming every such blocked program into an equivalent terminating program.

See [6, 9] for details about this transformation.

Using such an example, we are also able to show that our deductive system can deal with more general invariance or safety properties (in the terminology of [13]) than just partial correctness.

The program \( P \) consists of \( n \) parallel processes arranged in a ring configuration, where each processes \( P_i \) communicates with its own immediate neighbours \( P_{i-1}, P_{i+1} \) ('+' and '-' are interpreted cyclically in \( \{1, \ldots, n\} \)). Each process has a local variable \( x_i \) which initially has the value \( \sigma_i \). Each process sends its own \( x_i \) to each immediate neighbour, and uses flags \( \text{rs}l \) (ready to send \( \text{left} \)) and \( \text{rs}r \) (ready to send \( \text{right} \)) to avoid sending \( x_i \) again before it was modified. Other alternatives of \( P_i \) are to receive a copy of \( x_{i-1} \) in \( y \), or a copy of \( x_{i+1} \) in \( z \). Upon receiving such a number from a neighbour process, the number is compared to \( x_i \). If \( x_i \) is larger, then it is updated according to Euclid's rule, and the \( \text{rs}l \), \( \text{rs}r \) flags are set on. Otherwise nothing happens. Two auxiliary variables \( \text{rc}v\_l \) (received from \( \text{left} \)) \( \text{rc}v\_r \) (received from \( \text{right} \)) are included for the sake of the proof.

Since the program deadlocks upon reaching the final state, no post-condition is claimed for the whole program. Rather, we shall show to express in the formalism the claim about the state at the instant of blocking.
In the annotation $LI_i$ is the loop invariant of $P_i$ which serves also as the pre-condition and post-condition for the body of the main loop.

Following is the annotated text for $P_i$:

\[
\begin{align*}
\{x_i = \sigma_i > 0 \land rsl_i \land rsr_i \}
\end{align*}
\]

\[\begin{align*}
&\{LI_i\} \\
&\langle rsl_i, P_{i-1}!x_i \rightarrow rsl_i := \text{false}; rcvl_i := \text{false} \rangle \{LI_i\} \\
\end{align*}\]

\[\begin{align*}
&\langle rsr_i, P_{i+1}!x_i \rightarrow rsr_i := \text{false}; rcvr_i := \text{false} \rangle \{LI_i\} \\
\end{align*}\]

\[\begin{align*}
&\langle P_{i-1}?y_i \rightarrow rcvl_i := \text{true}; \\
&\quad [y_i \geq x_i \rightarrow \text{skip} \\
&\quad y_i < x_i \rightarrow [y_i | x_i \rightarrow x_i := y_i \\
&\quad \quad [y_i \mid x_i \rightarrow x_i := x_i \mod y_i \\
&\quad \quad \quad ]; \{LI_i\} \quad rsr_i := \text{true}; rsl_i := \text{true} \\
\end{align*}\]

\[\begin{align*}
&\langle P_{i+1}?z_i \rightarrow & rcvr_i := \text{true}; \\
&\quad [z_i \geq x_i \rightarrow \text{skip} \\
&\quad z_i < x_i \rightarrow [z_i | x_i \rightarrow x_i := z_i \\
&\quad \quad [z_i \mid x_i \rightarrow x_i := x_i \mod z_i \\
&\quad \quad \quad ]; \{LI_i\} \quad rsr_i := \text{true}; rsl_i := \text{true} \\
\end{align*}\]

\[\]

The global invariant, GI, is the following:

\[
\begin{align*}
GI = \bigwedge_{i=1}^{n} \left[ \neg rsl_i \rightarrow (z_{i-1} = x_i \land rcvr_{i-1}) \right. \\
\left. \land \neg rsr_i \rightarrow (y_{i+1} = x_i \land rcvl_{i+1}) \right. \\
\left. \land \gcd(x_1, \ldots, x_n) = \gcd(\sigma_1, \ldots, \sigma_n) \right]
\end{align*}
\]

GI establishes the correct sending and receiving relationship between any triple $P_{i-1}, P_i, P_{i+1}$, and also that all changes in the $x_i$'s preserve $\gcd(\sigma_1, \ldots, \sigma_n)$. 

The loop invariant $LI_i$ is expressed in terms of local variables (of $P_i$) only, and describes the sequential behaviour of the loop body:

$$LI_i = (\neg rsl_i \land rcv_i \rightarrow y_i \geq x_i)$$

$$\land (\neg rsr_i \land rcvr_i \rightarrow z_i \geq x_i).$$

The instant where a process is about to execute the loop body and find itself blocked is characterized by

$$BL_i = (LI_i \land \neg rsl_i \land \neg rsr_i).$$

Therefore, we have to prove the following property:

$$(*) \quad (GI \land \bigwedge_{i=1}^n BL_i) \rightarrow (\bigwedge_{i=1}^n x_i = \gcd(\sigma_1, \ldots, \sigma_n));$$

$$(*)$$ implies that the conclusion indeed holds at the instant of total blocking if it occurs.

Proof of $(*):$ Suppose that $GI \land \bigwedge_{i=1}^n BL_i$ holds.

From $GI \land \bigwedge_{i=1}^n (\neg rsl_i \land \neg rsr_i)$ we infer

$$(1) \quad \bigwedge_{i=1}^n (x_i = z_{i-1} = y_{i+1}) \land rcvr_i \land rcvl_i.$$

From $\bigwedge_{i=1}^n (LI_i \land \neg rsl_i \land \neg rsr_i \land rcvl_i \land rcvr_i)$ we infer

$$(2) \quad \bigwedge_{i=1}^n (y_i \geq x_i \land z_i \geq x_i).$$

Using (1) and (2) we get

$x_i \leq z_i = x_{i+1}$

and

$x_{i+1} \leq y_{i+1} = x_i$ which, together, imply

$$(3) \quad x_i = x_{i+1}, \text{ and therefore}$$

$$(4) \quad x_i = x_2 = \ldots = x_n.$$

Finally, (4) and $\gcd(x_1, \ldots, x_n) = \gcd(\sigma_1, \ldots, \sigma_n)$ imply the required conclusion $\bigwedge_{i=1}^n x_i = \gcd(\sigma_1, \ldots, \sigma_n).$

We are left with the problem of verifying that $GI$ is indeed a global invariant, and $LI_i$ is a local loop invariant. The second task involves ordinary sequential reasoning using the input and output axioms, and is left to the reader.

On the other hand, a proof of the global invariance of $GI$ uses the concept of cooperation.

(a) Initially, $\bigwedge_{i=1}^n \neg rsl_i \land \neg rsr_i$ is false, and the two first clauses of $GI$ are trivially true. Also $\bigwedge_{i=1}^n x_i = \sigma_i$ trivially implies the third clause.
(b) One pair of matching bracketed sections is the one consisting of the first alternative of some \( P_{i-1} \) and the fourth alternative of \( P_{i-1} \). Hence, we have to show:

\[
\{ rsl_i \land LI_i \land LI_{i-1} \land GI \}
\]

\[
P_{i-1}'x_i \; ; \; rsl_i := \text{false}; \; rcv_i := \text{false} \tag{A}
\]

\[
P_{i}'z_{i-1}' \; ; \; rcvr_{i-1} := \text{true}; \; [...] \tag{B}
\]

\[
\{ LI_i \land LI_i \land GI \}
\]

The variables changed are: \( rsl_i, rsl_{i-1}, rsr_{i-1}, rcv_i, rcv_{i-1}, z_{i-1}, x_{i-1} \).

By the rule of \textit{formation} it remains to be proved that:

\[
\{ x_i = z_{i-1} \land rsl_i \land LI_i \land (\neg rsr_{i-1} \land rcv_{i-1} \rightarrow y_{i-1} \geq x_{i-1}) \land GI \}
\]

\[ A; B \]

\[
\{ LI_i \land LI_{i-1} \land GI \}
\]

holds, where the above pre-condition is the post-condition of:

\[
P_{i-1}'x_i \parallel P_{i}'z_{i-1}
\]

inferred by the axioms of communications and preservation.

First, \( x_i = z_{i-1} \) implies, by the known mathematical facts about the \( \text{gcd} \) function, that \( \text{gcd}(x_1, ..., x_n) = \text{gcd}(a_1, ..., a_n) \) remains true after executing \( A; B \).

All other changes need just routine checks.

(c) The other matching bracketed sections are the second alternative of \( P_i \) and the third alternative of \( P_{i+1} \) and are verified similarly.

4. \textbf{DEADLOCK FREEDOM}

Similarly as in [17, 18], we wish to use our proof system to show that a given program is deadlock free. For this purpose, however, our system as presented so far is incomplete, in contrast to [17, 18], and has to be strengthened. The resulting system can also be used to prove the absence of failure due to attempts at communication with processes that already terminated. These questions do not arise in the work of Owicki and Gries, because the distributed termination convention cannot be described in the programming languages which they consider.

We adapt the concept of \textit{blocking} as introduced in [18]. This concept is used to characterize those states in which execution cannot be continued. Our version takes additionally the distributed termination convention of CSP into account in that communication at the guards of an \textit{if} guarded \textit{repetition} will \textit{not be blocked} in case all the processes referred to in the guards with a \textit{true} boolean component have terminated. All other communications which address processes
that have terminated will be blocked. Intuitively, a program is blocked (in a
given state) if the set of processes which did not terminate as yet is not
empty, all are waiting for communication, and there exists amongst them no
pair of processes which wait for each other, one for input and the other for
output; and also, there exists no process in that set which would exit a
loop by the distributed termination convention. Thus in a blocked state no
process can proceed.

Given a program $P$ and an initial assertion $p$, we say that $P$ is deadlock
free (relative to $p$) if no execution of $P$, starting in an initial state
satisfying $p$, can reach a state in which $P$ become blocked.

We proceed with the formal definitions required in order to formulate
the theorem about deadlock freedom. We assume that a specific proof outline
is given for each process $P_i$, $i = 1, \ldots, n$. Let $I$ be the global invariant
associated with the proof.

First we describe a blocked situation. A blocked situation is
characterized by an $n$-tuple of sets of communication capabilities associated
with the corresponding processes.

Assume that each process waits for a communication or has terminated.
Then its communication capabilities are introduced as follows:

i) If a process waits in front of an i/o command which is not a guard
then the bracketed section surrounding this i/o command constitutes
its only communication capability.

ii) If a process waits in front of an alternative or repetitive command
then a (possibly empty) subset of the set of all bracketed sections
containing the i/o guards of that command form its set of communication
capabilities. This subset corresponds to those guards whose boolean
part evaluate to true.

iii) If a process terminated than its only communication capability
consists only of acknowledging its termination.

Now, a situation is blocked if all of the following clauses hold:

a) In the $n$-tuple of sets of communication capabilities there does
not exist a matching pair of bracketed sections.

b) If a process waits in front of a repetitive command then its set
of communication capabilities is nonempty and not all processes
(which are addressed in the bracketed sections) from its sets of
communication capabilities acknowledge their termination.

c) Not all processes acknowledge their termination.
To illustrate the concepts introduced above, consider the following examples. In all of them we consider the situation in which each process waits to begin, so clause c) applies trivially.

1) Let $P ::= [P_1 :: P_2!x \parallel P_2 :: P_1'y]$. Then clause a) clearly holds and b) is obviously satisfied, so $P$ is blocked.

2) Let $P ::= [P_1 :: P_2!x \parallel P_2 :: P_1'y]$. Then clause a) does not apply, so the situation is not blocked.

3) Let $P ::= [P_1 :: *P_2?x \rightarrow S] \parallel P_2 :: P_1'y]$. Then both a) and b) hold, so the situation is blocked.

4) Let $P ::= [P_1 :: *P_2?x \rightarrow S] \parallel P_2 :: P_1'y]$. Then b) holds but a) doesn't, so the situation is not blocked.

5) Let $P ::= [P_1 :: [false, P_2?x \rightarrow S] \parallel P_2 :: P_1'y]$. Then the set of communication capabilities of $P_1$ is empty because the boolean guard of the loop is identically false. Thus b) does not apply and the situation is not blocked. Indeed, $P_1$ can exit the loop, and then a blocked situation does arise indeed.

6) Let $P ::= [P_1 :: [false, P_2?x \rightarrow S] \parallel P_2 :: P_1'y]$. Then both a) and b) (notice that $P_1$ is a guarded selection!) are satisfied and the situation is blocked.

Next, we associate with each blocked situation an $n$-tuple of assertions. We intend to prove that program $P$ is deadlock free (relative to assertion $p$) by checking that all blocked situations give rise to unsatisfiability of the global invariant $I$ and all assertions associated with that situation.

In the subsequent discussion the following notation will be useful.

Let $S$ be an alternative statement $[O (j = 1, \ldots, m) b_j, \alpha_j \rightarrow S_j]$ or a repetitive statement $*[O (j = 1, \ldots, m) b_j, \alpha_j \rightarrow S_j]$ and let $A \subseteq \{1, \ldots, m\}$. By $\text{pre}(S, A)$ we shall mean the assertion $\text{pre}(S) \land \bigwedge_{j \in A} b_j \land \bigwedge_{j \notin A} \neg b_j$.

Consider now a blocked situation. Let $P_i$ be one of the blocked processes. We associate with $P_i$ an assertion $p_i$:

a) If $P_i$ is in the situation as described in (i) above then $p_i$ is the pre-assertion of the corresponding bracketed section.

b) If $P_i$ is in the situation as described in (ii) above then $p_i$ is $\text{pre}(S, A)$ where $S$ is the guarded command in front of which $P_i$ waits and $A$ is the set of indices corresponding with the set of communication capabilities of $P_i$.

c) If $P_i$ is in the situation as described in (iii) above then $p_i$ is $\text{post}(P_i)$.
We call an n-tuple \( < p_1', \ldots, p_n > \) of assertions associated with a blocked situation a blocked n-tuple.

Then the following theorem holds:

**Theorem 1**: Given a proof of \( \{ p \} P \{ q \} \) with global invariant \( I \), then \( P \) is deadlock free (relative to \( p \)) if for every blocked n-tuple 
\( < p_1', \ldots, p_n > \) \( \forall i \in [1, n] \ (p_i \land I) \) holds. \( \Box \)

Hence, in order to prove that \( P \) is deadlock free, we have to identify all blocked tuples of assertions, and the global invariant \( I \) should be such that a contradiction can be derived from the conjunction of the invariant and the given blocked tuple. The operational meaning of this contradiction is as follows: there is no moment during execution at which control of every \( P_i \) reaches a point in which the assertion \( p_i \) (taken from the given blocked tuple) holds. If the conditions of the theorem hold then execution can proceed smoothly (possibly forever).

The theorem above is a consequence of the following one, whose proof is part of the proof of the soundness and completeness of the system, to be published by the first author.

**Theorem 2**: Let a proof of \( \{ p \} P \{ q \} \) be given. If during execution of \( P \) starting in a state satisfying \( p \), each \( P_i \) is about to execute a statement with a pre-assertion \( \text{pre}_i \), then \( \forall i \in [1, n] \ \text{pre}_i \) is satisfied by the (global) state at that moment. If \( P_i \) terminated then \( \text{post}(P_i) \) holds.

If none of the processes is within a bracketed section then \( I \) holds. \( \Box \)

To illustrate the use of theorem 1 we now prove deadlock freedom of the programs considered in examples 1, 3 and 4 of section 2.

To deal with the program from example 1, \( \{ P_1 \land P_2 \land P_3 \} \{ P_2?'x \mid P_2 \land P_3?'y \mid P_3 \land P_2?'u \} \), we need the following new proof outlines:

\( \{ i = 0 \} < P_2?'x; i = 1 > \{ i = 1 \} \),
\( \{ j = 0 \land k = 0 \} < P_1?'y; j := 1 >; \{ j = 1 \land k = 0 \} \),
\( < P_3?'y; k := 1 >; \{ j = 1 \land k = 1 \} \),
\( \{ \ell = 0 \} < P_2?'u; \ell := 1 >; \{ \ell = 1 \} \).

Let \( I = i = j \land k = \ell \).

The proofs clearly cooperate and can be used to establish the rather unimpressive fact that \( \{ \text{true} \} \{ P_1 \land P_2 \land P_3 \} \{ \text{true} \} \) holds. On the other hand the above proof outlines are sufficient for the proof of deadlock freedom. It is easy to see that the conjunction of any blocked triple of assertions implies
\[ i \neq j \lor k \neq i \] which is incompatible with \( I \). By theorem 1, \( [P_1 \parallel P_2 \parallel P_3] \) is deadlock free relative to \( \text{true} \).

Having dealt with i/o commands only, let us now consider a program containing an i/o guarded alternative statement, namely the program from examples 3 and 4, \( [P_1 :: [P_2 ?x \rightarrow \text{skip} \parallel P_2 !0 \rightarrow P_2 ?x; x := x + 1] \parallel P_2 :: [P_1 ?2 \rightarrow \text{skip} \parallel P_1 ?z \rightarrow P_1 !1]] \). In this case the proof outlines given in example 4 are sufficient to show deadlock freedom relative to \( \text{true} \). The analysis is simplified by the fact that the boolean guards of the alternative statements are identical to \( \text{true} \); this implies that any process waiting to start has exactly two communication capabilities.

In particular the situation when one process waits to start and the other did not terminate is not blocked. The only situation which is blocked is when one process waits to start and the other terminated. The corresponding pair of blocked assertions implies then \( i \neq j \) which is incompatible with the global invariant \( I \equiv i = j \).

Let us now turn our attention to programs containing an i/o guarded repetitive command. One of the simplest examples is a program of the form \( [\text{skip} \parallel *[\alpha \rightarrow \text{skip}]] \). This program is clearly deadlock free relative to \( \text{true} \) and the proof of this fact is trivial — according to the definitions there is simply no blocked situation, so no blocked pair of assertions needs to be considered.

We are less lucky when trying to prove deadlock freedom of the program \( \overline{\alpha} \parallel *[\alpha \rightarrow \text{skip}] \). In spite of our elaborated definitions it is impossible to prove with our method that the above trivial program is deadlock free relative to \( \text{true} \)!

The easiest way to see this is as follows:

1) The only formally blocked situation is the one when the first process waits to start and the second terminated. Of course such a situation cannot occur operationally but our definitions above do not rule this situation out.

2) Consider now a new, fictitious interpretation of i/o guarded repetitive commands according to which the loop can also be exited immediately. Our rule for i/o guarded repetition is still sound under this interpretation and the description of blocked situations still applies to the new interpretation. As a result both theorem 1 and 2 remain valid. If we were now able to prove the required premise of theorem 1 in the case of the above program then this program were deadlock free relative to \( \text{true} \) under the new interpretation. But the latter is clearly not the case since the new interpretation makes now the only formally blocked situation reachable.
Note that the above reasoning does not contradict the relative completeness of the introduced proof system for partial correctness. Namely if \( (p) \ P \ (q) \) is true under the usual interpretation then it is true under the new interpretation, so the above argument does not apply any more.

One is tempted to consider the above situation where the first process waits to start and the other terminated as not blocked. However, such a solution does not work with more complicated programs, e.g., when \( P_2 \) is of the form \( [*[false \to *[\alpha \to \text{skip}]]] \).

We conclude that the present system is inadequate to reason about deadlock freedom, since its underlying interpretation can be changed so as to rule out the example of formal blocking considered above, while keeping axioms and proof rules satisfied.

To remedy the situation we introduce local propositional variables \( \text{End}^i_j, i \neq j, 1 \leq i, j \leq n \), with the following interpretation: \( \text{End}^i_j \) holds if \( P_i \) "assumes" that \( P_j \) terminated. These propositional variables have false as their initial truth value. When they are included in some assertion with true as their truth value, it will be only due to a loop exit in some process. In the proof (but not in the program) this change of value will be described as if assignments take place upon loop exit. \( \text{End}^i_j \) can only be used in proofs concerning \( P_i \).

The new rule for i/o guarded repetition becomes now

\[
\text{R2'} \quad \text{guarded repetition}
\]

\[
\frac{(p \land b_j)}{\{ p \mid (j = 1, \ldots, m) b_j \land \alpha_j \Rightarrow S_j \}} \{ p \land \bigwedge_{j \in A} (\neg b_j \lor \text{End}^i_k) \}
\]

Here \( k_j \) denotes the index of the process referred to by \( \alpha_j \), and \( i \) denotes the index of the process containing the loop.

The propositional variables \( \text{End}^i_j \) are used in general in the global invariant \( I \) so setting them to true can affect the invariant indeed. Therefore, we must add a clause to the definition of cooperation.

The clause to be added is the following:

iii) Let \( S \) denote a subprogram of \( P_i \) of the form

\[
*[ \{ q \mid (j = 1, \ldots, m) b_j \land \alpha_j \Rightarrow S_j \}]
\]

Let \( A \subseteq \{ 1, \ldots, m \} \) and let \( C \) be the set of indices of all processes referred to in \( \alpha_j \) for \( j \in A \). Then \( \bigwedge_{j \in C} \text{post}(P_j) \land \text{pre}(S, A) \land I \Rightarrow (\text{post}(S) \land I) \) holds.

Here \( q \{ \text{true/End}^i_j \mid j \in C \} \) stands for the formula obtained from \( q \) by simultaneous substitution of \( \text{true} \) for \( \text{End}^i_j, j \in C \).
The above clause states that if process $P_i$ is about to exit an i/o guarded repetition (which is expressed by the left hand side of the formula) then the exit itself (modelled by setting the corresponding $\text{End}_j^i$ variables to $\text{true}$) both preserves the invariant and establishes the post-condition of the loop. The other assertions do not use $\text{End}_j^i$ variables so cannot be affected by the exit.

The adopted changes retain the validity of theorem 1.

A simple example serves to illustrate the introduced concepts. Consider the program $P :: (\alpha \parallel \{ \alpha \rightarrow \text{skip} \})$ (which caused our troubles originally) with the following proof outlines:

\[
\begin{align*}
\{ i = 0 \} < \alpha; \ i := 1 > \{ i = 1 \}, \\
\{ \neg \text{End}_1^2 \} \{ \alpha \rightarrow \text{skip} \} \{ \text{End}_1^2 \},
\end{align*}
\]

and let $I = \text{End}_1^2 \rightarrow i = 1$.

All omitted assertions are equal to $\text{true}$. The second proof outline makes use of rule R2'. The proofs cooperate - the new clause of cooperation $i = 1 \land \text{true} \land I \rightarrow (\text{End}_1^2 \land I) [\text{true} / \text{End}_1^2]$ clearly holds.

The only blocked situation leads to a blocked pair $< i = 0, \text{End}_1^2 >$ of assertions which are clearly incompatible with $I$. The proof outlines are sufficient to establish the proof of $\{ \text{true} \} P \{ \text{true} \}$. By theorem 1 $P$ is deadlock free relative to $\text{true}$.

Now we apply these new concepts to the partition example considered in section 3. We refer to the proof presented there.

In order to prove the absence of deadlock in this program, we have to strengthen the invariant $\text{GI}$ to include

\[
\text{GI}' = \text{End}_1^2 \rightarrow mx \leq x,
\]

and add $mx > x$ to the pre-condition of the two bracketed sections in the loop of $P_1$, as well as adding $mx \leq x$ to the post-condition of $P_1$. Also, the use of the strong version of i/o guarded repetition rule implies that $\text{End}_1^2$ is added to post ($P_2$). In showing the cooperation of proofs, the only new case that has to be checked is the loop exit of $P_2$; since we can assume post ($P_1$), $\text{GI}'$ holds indeed.

Next, we consider all blocked pairs $< p, q >$ of assertions, and show that their conjunction with $\text{GI} \land \text{GI}'$ is contradictory.

In all cases which do not involve the post-assertions of $P_1$ or $P_2$ the contradiction is reached by observing that all blocked pairs imply different parities of the $l_i$'s whereas $\text{GI}$ implies $l_1 = l_2$. 
For example, with $p$ as the pre-assertion of $P_1$'s first bracketed section and $q$ as the pre-assertion of $P_2$'s first bracketed section inside its loop, we have

$$\ell_1 = 0 \land \text{odd} \ (\ell_2) \land \ell_1 = \ell_2$$

which is contradictory.

The only other case with an essentially different proof, which does not use the fact that GI implies $\ell_1 = \ell_2$, is when $p$ denotes the pre-assertion of $P_1$'s first bracketed section inside its loop and $P_2$ has terminated, i.e. $q$ contains $\text{End}^2_1$ (amongst others). Then we have

$$\text{mx} > x \land (\text{End}^2_1 \rightarrow \text{mx} \leq x) \land \text{End}^2_1$$

which again is contradictory.

Note that only here the additional invariant GI' was used.

Returning to the gcd program from section 3, we will prove that there is no other blocking possibility in that program besides the intended one (as stated in the explanation to the program).

Let $\text{GI'} \equiv \bigwedge_{i=1}^n (\text{End}_i \land \text{End}^i_1)$.

We shall prove the invariance of GI'. By using the strong repetition rule R,' we get that each post($P_1$) implies

$$\text{End}^i_1 \land \text{End}^i_1$$

(by considering the third and fourth alternatives of each loop). Initially GI' holds, since all $\text{End}^i_j$ are initially false.

All we have to consider now is a loop exit of some $P_i$, and then

$$\text{post}(P_1) \land \text{post}(P_i)$$

may be assumed, i.e. we have to verify

$$\text{GI'} \land \text{End}^1_i \land \text{End}^{-1}_i \rightarrow (\text{GI'} \land \text{End}^1_i \land \text{End}^{-1}_i)$$

which trivially holds.

A simple consequence of GI' is

$$**; \bigwedge_{i=1}^n \text{End}^i_1 = \text{End}^j_1$$

The meaning of this condition is that either all processes have terminated, or none did.

Any blocked tuple of assertions (besides the one considered in section 3) implies that some of the assertions in the tuple are post($P_1$) for some $1 \leq i \leq n$, i.e. that some (but not all) of the processes terminated, which clearly contradicts (**).
In order to conclude that the situation considered in section 3 does occur (i.e. is inevitably reachable) we have to use:

i) A well-foundedness argument to prove the absence of infinite computations.

ii) The distributed termination pattern theorem [6] to show that the program does not terminate, since its termination dependency graph is cyclic.

iii) The absence of other blocked tuples of assertions than the one considered in section 3, as was shown above.

The proof of (i) is beyond the scope of the present paper and therefore omitted.

5. CONCLUSION AND COMPARISON WITH RELATED WORK

We have presented a proof system for partial correctness and absence of deadlock in CSP programs. Now that have gone through all stages of its development, it may be useful to compare our proof system with related Hoare-style proof systems dealing with concurrency.

As we see no way of improving in this respect upon Leslie Lamport's lucid comments upon our paper we feel justified in citing him in extenso:

"This paper provides a method for proving safety properties (the generalization of partial correctness properties) of programs written in CSP. Proving such properties requires proving that if the program is started in a valid initial state, then a certain assertion will always remain true. This in turn is proved by showing that some assertion \( I \) is invariant - i.e., if the program is started in any state in which \( I \) is true, then \( I \) remains true.

The simplest approach to proving the invariance of \( I \) is to show that each atomic action of the program leaves \( I \) true. This approach was first described by Ashcroft [1]. The next approach, taken by Owicki and Lamport, takes into account the structure of ordinary multiprocess programs, in which each atomic action occurs as the result of executing one "program step" in some process. The invariant assertion \( I \) is written as the conjunction of assertions of the form "control at \( x \rightarrow I(x)\)", where \( I(x) \) is the assertion "attached to" control point \( x \). To prove invariance of \( I \), one proves the following for each control point \( x \).

If \( I(x) \) is true, control is at \( x \), and executing the program step at \( x \) leaves control at \( x' \), then:

1. \( I(x') \) is true after execution.
2. For each control point \( y \) in every other process, if \( I(y) \) is true before the execution and control is at \( y \), then \( I(y) \) is true after the execution.
The second part of the conclusion was called "interference freedom" by Owicki. This method can be viewed as a special case of Ashcroft's method, in which the assertion I has a special form. Conversely, Ashcroft's method can be viewed as the special case of Owicki's and Lamport's in which the single assertion I is attached to all control points. (This illustrates the futility of trying to decide whether one method is more general than another).

Because the same assertion is attached to each location, part 2 (interference freedom) of the conclusion is implied by part 1, so no explicit proofs of interference freedom are needed by Ashcroft's method. However, this provides no real advantage since the same amount of verification is required in both methods: the interference freedom proofs appear in Ashcroft's method as the extra complexity of proving that the larger monolithic assertion I is left true by each atomic operation. The difference in the two methods is largely a matter of syntactic convenience. The interference freedom method is more convenient when the global invariant assertion I is conveniently written as the conjunction of assertions I(x) attached to program control points. Ashcroft's method is more convenient when the invariant I is simple and does not need to be decomposed.

In Owicki's treatment, the assertions I(x) could not explicitly mention program control points. This meant that she had to introduce auxiliary variables, instead.

Now suppose we consider a more general multiprocess programming language, in which program steps in one or more different processes may be executed simultaneously as one single step. Let us call \( \{x_1, \ldots, x_i\} \) a multicontrol point if the program steps at control points \( x_1, \ldots, x_i \) are steps which may be executed simultaneously in this way - where each of the \( x \)'s is in a different process. (The singleton \{x\} is a multicontrol point if the program step at x is a local one, which can be executed by itself.) If \( x = \{x_1, \ldots, x_i\} \), define I(x) to be the conjunction of the assertions I(x_1), ..., I(x_i). The above Owicki/Lamport proof rule can then be generalized by replacing the single control points x and x' by multicontrol points, where "control at x" is defined in the obvious way for a multicontrol point x. (In the new definition, y remains an ordinary [single] control point.) (This methodology was independently developed by Mazurkiewicz [15] where simultaneous await - statements are considered. - our remark.)

This approach obviously provides a proof methodology for CSP, where the non-local multicontrol points involve I/O statements. (The actual transition from proof methodology to proof system is achieved by providing suitable axioms and proof rules, such as the communication axiom, which enable incorporation of the above generalization of condition 1 (i.e. cooperation) into the proof system - our remark.) The proof method presented in the present paper can be derived as follows
as a special case of this general method, based upon the fact that syntactic restrictions on the type of assertions that can be used make certain verifications unnecessary. First of all, the CSP language is generalized by introducing the "bracketed sections". The bracketing defines the non-local atomic operations. The rules for what may appear inside brackets are codifications of the well-known fact that operations that affect only local variables may be subsumed within an adjacent atomic operation. (In particular, it doesn't make any difference how the local atomic operations are defined.)

The non-local multicontrol points are the control points at the beginning of the bracketed statements. The assertion I(y) attached to each control point y is of the form "I'(y) and I", where I'(y) is the assertion explicitly attached to y, and I is the "global invariant". The separation of the proof into a local proof and a proof of "cooperation" involves the separation into local control points (singleton multicontrol points) and non-local control points. Axioms A1 and A2 simply enforce that the statements involving I/O concern non-local control points, and are not considered by the local proof.

The fact that no interference freedom proofs are necessary is an immediate consequence of the restriction that the assertion attached to each control point y is of the form "I'(y) and I", where I'(y) contains variables only modified by that process. (The same remark applies to the proof system considered in [17] — our remark.) No interference proofs are needed for precisely the same reason that they are not needed in Ashcroft's method: because the only non-local assertion is attached to all control points. The global assertion I does not have to appear in the local part of the proof because of the assumption that it contains no variables that can be set by other local operations". (End of quote from Lamport's comments.)

In the present paper program control is modelled by the use of auxiliary variables and the global invariant. A different approach (suggested by L. Lamport) can be envisaged here, in which program control variables are explicitly allowed to appear in assertions making the use of the global (monolithic) invariant unneeded.

A full discussion of the relative merits of these two alternative approaches, i.e. auxiliary variables versus program control variables, is beyond the scope of the paper. We mention only that program control variables lead in general to nonrecursive intermediate assertions (see [2]).
It is also possible to have a proof system for CSP without global invariant, in which only shared auxiliary variables are used. An example is the proof system presented in [14] where the component proofs have to be checked both for interference freedom and cooperation, since auxiliary variables can be shared.

One of the features of our system is that the cooperation test requires us to supply new formal proofs which do not constitute a part of the (sequential) proof outlines. This phenomenon is also present in [18] where new proofs are needed to show interference freedom. These proofs can be viewed as global reasoning since they involve more than one process. In our case the bigger the bracketed sections the more sizeable proofs have to be carried out. The (to be published) proof of relative completeness of our system implies that we can always choose bracketed sections of the form \( \text{assignment} \); \( S \) where \( S \) is an assignment (for updating the local history of communications), thus reducing global reasoning.

Our method suffers from the same drawback as the one presented in [18]; in the worst case the test for cooperation, e.g. for the case of two processes, can involve as many as \( m_1 \times m_2 \) checks, where \( m_1 \) and \( m_2 \) are proportional to the lengths of the component programs. The same problem can arise in proofs of absence of deadlock. However, in practice the number of cases is significantly smaller, and often several of them can be trivially established, as is the case in testing cooperation between syntactically matching but semantically not matching pairs. For example, in our proof for the partitioning program 8 cases had to be established in the cooperation test and 15 for the proof of absence of deadlock, but only 4 cases have a not immediate proof of the cooperation test and only one such case occurs in the proof of absence of deadlock.

Finally, we summarize the results of this paper.

We have presented a system both for understanding and for proving correctness of CSP programs. The main aspect of this system is the notion of cooperating proof(outline)s. The arguments leading to the system as a whole have been motivated within the context of CSP. However Lamport's remarks seem to indicate that the notion of cooperating proof outlines is also essential for proving correctness of concurrent programs written in an extension of the usual shared variable framework with mutual synchronization (by means of "multi-control points").

CSP expresses distributed termination of processes. We illustrate this aspect in our system by proofs of two examples of distributed computation, one for partitioning a finite set, the other for computing the gcd of \( n \) numbers concurrently.
In order to prove absence of deadlock and failure (i.e. abortion) the proof system has to be strengthened. This is a consequence of CSP's distributed termination convention. The final system is obtained by adding the proof theoretical counterpart of this termination convention.
