Abstract

We introduce in this paper new communication and synchronization constructs which allow
deterministic processes, communicating asynchronously via unbounded FIFO buffers, to cope
with an indeterminate environment. We develop for the resulting parallel programming lan-
guage, which subsumes deterministic dataflow, a simple compositional proof system. Reason-
ing about communication and synchronization is formalized in terms of input/output variables
which record for each buffer the sequence of values sent and received. These input/output vari-
ables provide an abstraction of the usual notion of history variables which denote sequences of
communication events. History variables are in general necessary for compositional reasoning
about the correctness of distributed systems composed of non-deterministic processes.

1 Introduction

Hoare logics have been used successfully for reasoning about correctness of a variety of distributed
systems [OG76, AfR80, ZdR85, Pan88, HdR86]. In general, proof systems for distributed
systems based on some kind of Hoare logic formalize reasoning about communication and synchro-
nization in terms of sequences of communication events called histories.

Distributed systems based on synchronous communication allow an elegant compositional proof
theory [Zwi88] essentially because there exists a simple criterion for deciding when the local histories
of the processes of a system are compatible, that is, can be combined into a global history of the
entire system. This criterion consists of checking whether the local histories can be obtained as
some kind of projection of some global history.

On the other hand distributed systems based on asynchronous communication do not allow such
a simple criterion: To check the compatibility of the local histories one has in general to consider
all possible interleavings [Pan88]. As such its logical formulation will involve quantification over
histories, and this will obviously complicate the reasoning process.

The recent book on program correctness by Francez [Fra92] contains a section on non-determi-
nistic processes which communicate asynchronously via FIFO buffers, featuring a proof system that uses
a logic based on input/output variables instead of histories. A buffer is logically represented by an

*Part of this work is published in the Proceedings of Mathematical Foundations of Computer Science 1994
(MFCS'94), volume 841 of Lecture Notes in Computer Science
input variable which records the sequence of values read from the buffer and by an output variable which records the sequence of values sent to the buffer. The difference between input/output variables and histories is that in the former information of the relative ordering of communication events on different buffers is lost. However, it can be shown that this logic is incomplete for nondeterministic processes; the information expressible by input/output variables only is insufficient to obtain a complete specification of an entire system by composing the local specifications of its constituent processes.

The main contribution of this paper consists of showing that distributed systems composed of deterministic processes which communicate asynchronously via (unbounded) FIFO buffers, however do allow a simple complete compositional proof theory based on input/output variables. In order to endow a deterministic process with the capability of responding to an indeterminate environment we introduce communication and synchronization constructs which allow a process to test the contents of a buffer and to synchronize on a set of input buffers simultaneously. The resulting programming language subsumes deterministic dataflow. Thus despite the restriction to deterministic processes we obtain a powerful parallel programming language which still allows a simple compositional proof theory based on input/output variables.

The rest of this paper is organized as follows: In section 2, the programming language is defined. Then, in section 3, an operational semantics and a definition of correctness formulas and their semantics is given. In section 4, the proof system is presented, followed by the proofs of soundness (section 5) and completeness (section 6). Section 7 discusses an extension of the language which provides a process with the full means to cope with an indeterminate environment. Finally, section 8 contains some concluding remarks and observations.

2 The programming language

In this section, we define the syntax of the programming language. The language describes the behaviour of asynchronously communicating deterministic sequential processes. Processes interact only via communication channels which are implemented by (unbounded) FIFO-buffers. A process can send a value along a channel or it can input a value from a channel. The value sent will be appended to the buffer, whereas reading a value from a buffer consists of retrieving its first element. Thus the values will be read in the order in which they have been sent. A process will be suspended when it tries to read a value from an empty buffer. Since buffers are assumed to be unbounded sending values can always take place. Additionally we introduce constructs which allow testing whether a buffer is empty or not.

We assume given a set of program variables Var, with typical elements $x, y, \ldots$. Channels are denoted by $c, d, \ldots$.

**Definition 1** The syntax of a statement $S$ which describes the behaviour of a (deterministic) sequential process, is defined by

$$
S ::= \text{skip} \\
    \quad | \quad x := e \\
    \quad | \quad c??x | c!le \\
    \quad | \quad S_1; S_2 \\
    \quad | \quad \text{if } b \text{ then } S_1 \text{ else } S_2 \text{ fi} \\
    \quad | \quad \text{while } b \text{ do } S \text{ od} \\
    \quad | \quad \text{if } c??x \text{ then } S_1 \text{ else } S_2 \text{ fi} \\
    \quad | \quad \text{while } c??x \text{ do } S \text{ od} \\
    \quad | \quad \text{repeat } S \text{ until } c??x
$$
In the above definition skip denotes the ‘empty’ statement. In the assignment statement \( x := e \) we restrict for technical convenience to arithmetical expressions \( e \). Sending a value of an (arithmetical) expression \( e \) along channel \( c \) is described by \( e!c \), whereas storing a value read from a channel \( c \) in a variable \( x \) is described by \( c??x \). The execution of \( c??x \) is suspended in case the corresponding buffer is empty. Furthermore we have the usual sequential control structures of sequential composition, choice and iteration (\( b \) denotes a boolean expression). Additionally we allow as tests in the choice and while construct an input statement \( c??x \). The execution of a statement if \( c??x \) then \( S_1 \) else \( S_2 \) fi consists of reading a value from channel \( c \), in case its corresponding buffer is non-empty, storing it in \( x \) and proceeding subsequently with \( S_1 \). In case the buffer is empty control moves on to \( S_2 \). The execution of a statement while \( c??x \) do \( S \) od consists of alternatingly reading a value from channel \( c \) and executing \( S \) until the corresponding buffer is empty. Finally repeat \( S \) until \( c??x \) models a form of busy waiting: repeat \( S \) for as long as no value can be read from channel \( c \). Note that \( c??x \) is equivalent to repeat skip until \( c??x \), this corresponds to the ‘idle waiting’ inherent in \( c??x \). To resolve possible ambiguities in the grammar we assign to sequential composition the lowest binding priority.

**Definition 2** A parallel program \( P \) is of the form \([S_1 || \ldots || S_n]\), where we assume the following restrictions: the statements \( S_i \) do not share program variables, channels are unidirectional and connect exactly one sender and one receiver.

### 3 Semantics

In this section we define the operational semantics of the programming language and an appropriate notion of program correctness.

First we need to define the notion of state which assigns values to program variables and associates a FIFO buffer to each channel. For the formal justification of the compositional proof system it will appear to be convenient to introduce for each channel \( c \) variables \( c?? \) and \( c! \) which record the sequence of values read from channel \( c \) and the sequence of values sent along \( c \). The values read from a channel will also include a special value \( \bot \) which results from testing an empty buffer. For example a sequence \( (1, 2, 3, \bot, 4, 5) \) representing the values read from a channel indicates that after 1, 2 and 3 have been read the process tested the contents of the buffer when it was empty. Subsequent read operations on the channel resulted in the values 4 and 5. A variable \( c?? \) (\( c!! \)) is also called an input (output) variable. We denote the set of variables \( c?? \) and \( c!! \) by \( IO \).

**Definition 3** Restricting ourselves to the domain of values consisting of integers only, denoted by \( \mathbb{Z} \), the set of states \( \Sigma \), with typical element \( \sigma \), is defined as \( \Sigma = \{ \text{Var} \rightarrow \mathbb{Z}, IO \rightarrow \mathbb{Z}^{\bot} \} \).

In the above definition \( \mathbb{Z}^{\bot} \) denotes all finite sequences of elements of the set \( \mathbb{Z} \cup \{ \bot \} \). We introduce the following operations on sequences. The empty sequence is denoted by \( \epsilon \). Given a sequence \( s \in \mathbb{Z}^{\bot} \), its first element will be denoted by \( f(s) \), and the subsequence of \( s \) consisting of elements of \( \mathbb{Z} \) only we denote by \( r_\bot(s) \). The result of appending an element \( d \) to a sequence \( s \) is denoted by \( s \cdot d \). We define \( s \prec s' \) iff \( s \) is a prefix of \( s' \). By \( s' - s \) we denote the suffix of \( s' \) determined by its prefix given by \( s \) (so it is defined only if \( s \prec s' \)). The buffer corresponding to a channel \( c \) in a state \( \sigma \), that is, the sequence of values sent along \( c \) but not yet read, which we denote by \( \sigma(c) \), is given by \( \sigma(c!!) - r_\bot(\sigma(c??)) \). For example, if \( \sigma(c!!) = (1, 2, 3) \) and \( \sigma(c??) = (1, \bot, 2) \) then \( \sigma(c) = (3) \).

The value of a variable \( v \), which might be either a program variable \( x \) or an input/output variable \( c??, c!! \) in a state \( \sigma \) will be simply denoted by \( \sigma(v) \). Given a state \( \sigma \), a variable \( v \) and a value \( d \) (of
corresponding type), we define the state $\sigma\{d/v\}$ as follows:

$$\sigma\{d/v\}(v') = \begin{cases} 
\sigma(v') & \text{if } v \neq v' \\
\frac{d}{d} & \text{otherwise}
\end{cases}$$

The value of an arithmetical expression $e$ (boolean expression $b$) we denote by $\sigma(e)$ ($\sigma(b)$).

**Definition 4** A configuration is a pair $([S_1 || ... || S_n], \sigma)$, where $S_i$ is either a statement or equals $E$ which denotes termination.

We now define a transition relation $\rightarrow$ between configurations. For convenience, we identify the statements $S$ and $E$ for any statement $S$.

**Definition 5** The relation $\rightarrow$ between configurations is the smallest relation satisfying:

1. $\langle[... || skip; S || ...], \sigma \rangle \rightarrow \langle[... || S || ...], \sigma \rangle$
2. $\langle[... || x := e; S || ...], \sigma \rangle \rightarrow \langle[... || S || ...], \sigma\{\sigma(e)/x\} \rangle$
3. $\langle[... || c??; S || ...], \sigma \rangle \rightarrow \langle[... || S || ...], \sigma\{\sigma(c??) \cdot d/c??, d/x\}, \text{provided } \sigma(c) \neq \epsilon \text{ and } d = f(\sigma(c)) \rangle$
4. $\langle[... || c??x; S || ...], \sigma \rangle \rightarrow \langle[... || S || ...], \sigma\{\sigma(c??) \cdot d/c??, d/\emptyset\}, \text{provided } \sigma(c) \neq \epsilon \text{ and } d = f(\sigma(c)) \rangle$
5. $\langle[... || if \ b \ then \ S_1 \ else \ S_2 \ fi; S || ...], \sigma \rangle \rightarrow \langle[... || S_1; S || ...], \sigma \rangle, \text{provided } \sigma(b) = true$
6. $\langle[... || if \ b \ then \ S_1 \ else \ S_2 \ fi; S || ...], \sigma \rangle \rightarrow \langle[... || S_2; S || ...], \sigma \rangle, \text{provided } \sigma(b) = false$
7. $\langle[... || if \ c??r \ then \ if \ c??x \ then \ S \ od; S || ...], \sigma \rangle \rightarrow \langle[... || S || ...], \sigma\{\sigma(c??) \cdot \bot/c??, d/\emptyset\}, \text{provided } \sigma(c) \neq \epsilon \text{ and } d = f(\sigma(c)) \rangle$
8. $\langle[... || c??r \ then \ S_1 \ else \ S_2 \ fi; S || ...], \sigma \rangle \rightarrow \langle[... || S_2; S || ...], \sigma\{\sigma(c??) \cdot \bot/c??\}, \text{provided } \sigma(c) = \epsilon \rangle$
9. $\langle[... || while \ b \ do \ S \ od; S' || ...], \sigma \rangle \rightarrow \langle[... || S; while \ b \ do \ S \ od; S' || ...], \sigma \rangle, \text{provided } \sigma(b) = true$
10. $\langle[... || while \ b \ do \ S \ od; S' || ...], \sigma \rangle \rightarrow \langle[... || S' || ...], \sigma \rangle, \text{provided } \sigma(b) = false$
11. $\langle[... || while \ c??r \ do \ S \ od; S' || ...], \sigma \rangle \rightarrow \langle[... || S; while \ c??r \ do \ S \ od; S' || ...], \sigma\{\sigma(c??) \cdot d/c??, d/\emptyset\}, \text{provided } \sigma(c) \neq \epsilon \text{ and } d = f(\sigma(c)) \rangle$
12. $\langle[... || while \ c??r \ do \ S \ od; S' || ...], \sigma \rangle \rightarrow \langle[... || S' || ...], \sigma\{\sigma(c??) \cdot \bot/c??\}, \text{provided } \sigma(c) = \epsilon \rangle$
13. $\langle[... || repeat \ S \ until \ c??r; S' || ...], \sigma \rangle \rightarrow \langle[... || S; if \ c??r \ then \ skip \ else \ repeat \ S \ until \ c??r \ fi; S' || ...], \sigma \rangle$

It is worthwhile noticing that, although not strictly necessary for the definition of the operational semantics, recording tests on an empty buffer allow one to determine the local behaviour of a process. Consider the following two statements: $S = if \ c??r \ then \ d!!0; R_{1} \ else \ d!!0; c??r; R_{2} \ fi \ and \ S' = if \ d??r \ then \ c!!0; R'_{1} \ else \ c!!0; d??r; R'_{2} \ fi$. In case one does not record tests on an empty buffer
we cannot determine on the basis of the values of the input/output variables whether \( R_1 \) or \( R_2 \) (and, symmetrically, \( R'_1 \) or \( R'_2 \)) is reached in a computation of \([S \parallel S']\), which starts with empty buffers \( c \) and \( d \). This observation will play an important role in the completeness proof of the proof system.

**Definition 6** A computation sequence of a program \( P = [S_1 \parallel \ldots \parallel S_n] \) is a finite or infinite sequence \( C_0 \rightarrow C_1 \rightarrow \ldots \) of configurations such that \( C_0 = ([S_1 \parallel \ldots \parallel S_n], \sigma) \) for some state \( \sigma \).

We are now ready to define the semantics of a program:

**Definition 7** The semantics \([P](\sigma)\) of program \( P \) in state \( \sigma \) is defined as \( \{CS\} \) \( CS \) is a computation sequence of \( P \), and the state-component of the first configuration of \( CS \) equals \( \sigma \).

**Definition 8** A computation sequence of program \( P \) is terminating iff it is finite and its last configuration is \(([E \parallel \ldots \parallel E_1], \sigma)\), for some state \( \sigma \).

To reason about the correctness of a program we assume given some first-order logic (so we allow only quantification over \( \text{Var} \), not over \( \text{IO} \)) to describe properties of states. Thus the vocabulary of the logic includes the standard arithmetical operations and relations. Additionally we assume the logic to include operations and relations on sequences like append, prefixing, etc. Sequence terms of the logic are then constructed from the basic sequence terms \( c?? \) and \( c! \) using the included repertoire of sequence operations. The sequence term \( c \) representing the buffer associated with channel \( c \) we introduce as an abbreviation of the term \( c!! - r_1(c??) \). The truth of an assertion \( \phi \) in a state \( \sigma \) is denoted by \( \sigma \models \phi \). For example, \( \sigma \models c?? \prec c!! \) iff \( \sigma(c??) \prec \sigma(c!!) \).

The correctness of a program \( P \) will be specified in terms of formulas of the form \( I : \{\phi\}P\{\psi\} \), where \( I, \phi \) and \( \psi \) are assertions (of the given first-order logic). The assertions \( \phi \) and \( \psi \) are called the precondition and postcondition, respectively. The assertion \( I \) is called the (global) invariant, it expresses some invariant properties of the communication structure of a computation. As such a global invariant in general refers to sequence terms, no references to variables occurring in the program are allowed. Moreover, in \( I, \phi \) and \( \psi \) no quantification over the program variables of \( P \) may occur. Intuitively the meaning of a correctness formula \( I : \{\phi\}P\{\psi\} \) can be rendered as follows:

Every state of a computation of \( P \) starting in a state which satisfies both \( I \) and \( \phi \) satisfies \( I \), and upon termination \( \psi \) is guaranteed to hold.

Thus the formalism used here is a variant of \( I \)-logic, as introduced by Pandya [Pan88]. The following definition gives a more formal account of the semantics of correctness formulas:

**Definition 9** Given a correctness formula \( I : \{\phi\}P\{\psi\} \) such that \( I \) and \( P \) do not have program variables in common, we define \( \models I : \{\phi\}P\{\psi\} \) iff for any \( \sigma \), if \( \sigma \models I \land \phi \) then for all finite \( CS \in [P](\sigma), \sigma' \models I \) holds, where \( \sigma' \) is the second component of the last configuration of \( CS \); moreover if \( CS \) is terminating, then \( \sigma' \models I \land \psi \) holds.

### 4 The proof system

In this section we present the proof system for deriving correctness formulas. In order to reason about the correctness of a program \( P = [S_1 \parallel \ldots \parallel S_n] \) compositionally, that is, in terms of
the correctness of its parallel components $S_i$, we introduce local correctness formulas of the form $I : \{p\} S\{q\}$, where $I$ is a global invariant which does not contain occurrences of program variables of $S$, and $p$ and $q$ are assertions which are allowed only to refer to variables occurring in $S$. The set of variables of a statement $S$ consists of its program variables and those input/output variables $c?? (c!!)$ for which $c$ is an input channel of $S$ ($c$ is an output channel of $S$). We define the semantics of local correctness formulas axiomatically in terms of the following axioms and rules:

**Axiom 1** (skip) $I : \{p\} \text{skip}\{p\}$

**Axiom 2** (assignment) $I : \{p[e/x]\} x := e\{p\}$

**Rule 1** (output)

\[
\frac{(I \land p) \rightarrow (I \land q)[c!! \cdot e/c!!]}{I : \{p\} c!! e\{q\}}
\]

**Rule 2** (input)

\[
\frac{(I \land p \land c \neq e) \rightarrow (I \land q)[f(c)/x, c?? : f(c)/c??]}{I : \{p\} c?? x\{q\}}
\]

**Rule 3** (sequential composition)

\[
\frac{I : \{p\} S_1\{r\}, I : \{r\} S_2\{q\}}{I : \{p\} S_1; S_2\{q\}}
\]

**Rule 4** (conditional)

\[
\frac{I : \{p \land b\} S_1\{q\}, I : \{p \land \neg b\} S_2\{q\}}{I : \{p\} \text{if } b \text{ then } S_1 \text{ else } S_2 \{q\}}
\]

**Rule 5** (while loop)

\[
\frac{I : \{p \land b\} S_1\{p\}}{I : \{p\} \text{while } b \text{ do } S_1 \text{ od}\{p \land \neg b\}}
\]

**Rule 6** (input conditional)

\[
\frac{I : \{p\} c?? x; S_1\{q\}, (I \land p \land c = e) \rightarrow (I \land r)[c?? \cdot \perp/c??], I : \{r\} S_2\{q\}}{I : \{p\} \text{if } c?? x \text{ then } S_1 \text{ else } S_2 \{q\}}
\]

**Rule 7** (input while loop)

\[
\frac{I : \{p\} c?? x; S\{p\}, (I \land p \land c = e) \rightarrow (I \land q)[c?? \cdot \perp/c??]}{I : \{p\} \text{while } c?? x \text{ do } S_1 \text{ od}\{q\}}
\]

**Rule 8** (repeat)

\[
\frac{I : \{p\} S\{r\}, (I \land r \land c = e) \rightarrow (I \land p)[c?? \cdot \perp/c??], I : \{r\} c?? x\{q\}}{I : \{p\} \text{repeat } S \text{ until } c?? x\{q\}}
\]
Rule 9 (local consequence)

\[ I \land p \rightarrow p', I : \{p'\}S(q'), I \land q' \rightarrow q \]
\[ I : \{p\}S(q) \]

Note that we have assertions occurring as premises, that is, we assume as additional axioms all valid first-order assertions. In the axiom for the assignment statement we only need to substitute the expression \( e \) for \( x \) in the postcondition \( p \) since \( I \) is not allowed to refer to program variables. Thus \( I \) is on purely syntactical grounds invariant over assignments. The output statement \( c!! e \) is modeled as an assignment to the corresponding output variable \( c!! \) which consists of appending the value sent to the sequence \( c!! \). Since the global invariant may refer to the variable \( c!! \) we have to apply the corresponding substitution also to \( I \) itself. In a similar manner an input statement \( c?? x \) is modeled as a (multiple) assignment to the variable \( x \) and the input variable \( c?? \). To obtain a complete rule the enabledness condition of the input action, namely that the buffer \( c \) is non-empty, is included. (Note that the term \( c \) is actually an abbreviation of the term \( c!! - r_A(c??) \).) The following rules for the conditional and while statement are straightforward extensions of the usual rules. The rules for the conditional, while and repeat statement with an input statement as a test combine naturally the standard rules and the rule for input statements. The main additional feature is the recording of a test on an empty buffer. Finally, the local consequence rule extends in an obvious way the classical rule.

Local correctness formulas can be combined into correctness formulas of an entire program as follows:

Rule 10 (parallel composition)

\[ I : \{p_i\}S_{i}(q_i) (t = 1, ..., n) \]
\[ I : \{\bigwedge_i p_i\}S_1 \parallel ... \parallel S_n \{\bigwedge_i q_i\} \]

For completeness we need the following rules:

Rule 11 (consequences)

\[ I \land \phi \rightarrow I' \land \phi', I' : \{\phi'\}P(\psi'), I' \land \psi' \rightarrow \psi, I' \rightarrow I \]
\[ I : \{\phi\}P(\psi) \]

Rule 12 (substitution) Let \( v \) be a variable not occurring in \( P \) or \( q \), and \( t \) be a sequence term if \( v \) is an input/output variable, and an arithmetical term, otherwise.

\[ I : \{p\}P(q) \]
\[ I : \{p(t/v)\}P(q) \]

5 Soundness

In this section we will prove the soundness of the proof system, that is, we will argue that every derivable correctness formula \( I : \{\phi\}P(\psi) \) is valid. We will consider only the soundness of the parallel composition rule, the soundness of the consequence rule and the substitution rule being straightforward. Since the meaning of a local correctness formula is defined only axiomatically we introduce the notion of a local proof outline, and prove the soundness of the parallel composition rule by induction on the length of the computation of the program using information about the components as given by the local proof outlines.
In the following, we will need the syntactical continuations after(R, S) and before(R, S), where R is a substatement of S. Informally, they denote the part of S that remains to be executed after (before) R has been executed.

**Definition 10** Let S be some statement, and R some substatement of S. Define the syntactical continuations after(R, S) and before(R, S) as follows:

- If R = S then after(R, S) = E
- If S = if b then S₁ else S₂ fi or S = if c??x then S₁ else S₂ fi and R is a substatement of Sᵢ (i ∈ {1, 2}) then after(R, S) = after(R, Sᵢ)
- If S = while b do S₁ od or S = while c??x do S₁ od and R is a substatement of Sᵢ then after(R, S) = after(R, Sᵢ); S
- If S = repeat S₁ until c??x and R is a substatement of S₁ then after(R, S) = after(R, S₁); if c??x then skip else S fi
- If S = S₁; S₂ and R is a substatement of S₁ then after(R, S) = after(R, S₁); S₂; if R is a substatement of S₂ then after(R, S) = after(R, S₂)
- before(R, S) = R; after(R, S)

**Note:** We do not consider input commands occurring as tests in statement S to be substatements of S.

**Definition 11** Given a statement S, an invariant I and pre- and postcondition p and q, where p and q only contain variables occurring in S, a proof outline pfo(I, p, S, q) consists of the program text of S together with an assignment pre(R) and post(R) to all substatements R of S such that the following assertions are valid:

1. \((I \land p) \rightarrow \text{pre}(S)\) and \((I \land \text{post}(S)) \rightarrow q\)
2. \((I \land \text{pre}(R)) \rightarrow \text{post}(R), \text{for } R = \text{skip}\)
3. \((I \land \text{pre}(R)) \rightarrow \text{post}(R)[e/x], \text{for } R = x := e\)
4. \((I \land \text{pre}(R)) \rightarrow (I \land \text{post}(R))[c!! \cdot e/c!!], \text{for } R = c!!e\)
5. \((I \land \text{pre}(R) \land c \neq e) \rightarrow (I \land \text{post}(R))[f(c)/x, c?? \cdot f(c)/c??] \text{ for } R = c??x\)
6. \((I \land \text{pre}(R)) \rightarrow \text{pre}(R₁), \ (I \land \text{post}(R₁)) \rightarrow \text{pre}(R₂) \text{ and } (I \land \text{post}(R₂)) \rightarrow \text{post}(R), \text{ for } R = R₁; R₂\)
7. \((I \land \text{pre}(R) \land b) \rightarrow \text{pre}(R₁), \ (I \land \text{pre}(R) \land \lnot b) \rightarrow \text{pre}(R₂) \text{ and } I \land \text{post}(Rᵢ) \rightarrow \text{post}(R)(i = 1, 2), \text{ for } R = \text{if } b \text{ then } R₁ \text{ else } R₂ \text{ fi}\)
8. \((I \land \text{pre}(R) \land c \neq e) \rightarrow (I \land \text{pre}(R₁))[f(c)/x, c?? \cdot f(c)/c??], \ (I \land \text{pre}(R) \land c = e) \rightarrow (I \land \text{pre}(R₂))[c?? \cdot \bot/c??], \text{ and } I \land \text{post}(Rᵢ) \rightarrow \text{post}(R)(i = 1, 2), \text{ for } R = \text{if } c??x \text{ then } R₁ \text{ else } R₂ \text{ fi}\)
9. \((I \land \text{pre}(R) \land b) \rightarrow \text{pre}(R₁), \ (I \land \text{post}(R₁)) \rightarrow \text{pre}(R), \text{ and } (I \land \text{pre}(R) \land \lnot b) \rightarrow \text{post}(R) \text{ for } R = \text{while } b \text{ do } R₁ \text{ od}\)
10. \((I \land \text{pre}(R) \land c \neq e) \rightarrow (I \land \text{pre}(R_1))[f(c)/x, c??? \cdot f(c)/c???],\)
   \((I \land \text{post}(R_1)) \rightarrow \text{pre}(R),\) and \((I \land \text{pre}(R) \land c = e) \rightarrow (I \land \text{post}(R))[c??? \cdot \bot/c???],\)
   for \(R = \text{while} \ c??x \ do \ R_1 \ od\)

11. \((I \land \text{pre}(R)) \rightarrow \text{pre}(R_1),\)
   \((I \land \text{post}(R_1) \land c = e) \rightarrow (I \land \text{pre}(R))[c??? \cdot \bot/c???],\) and
   \((I \land \text{post}(R_1) \land c \neq e) \rightarrow (I \land \text{post}(R))[f(c)/x, c??? \cdot f(c)/c???],\)
   for \(R = \text{repeat} \ R_1 \ until \ c??x\)

The following lemma relates a proof of a local correctness formula with the existence of a local proof outline.

**Lemma 1** A local correctness formula \(I : \{p\}S\{q\}\) is derivable iff there exists a proof outline \(pfo(I,p,S,q)\).

**Proof** Only if: induction on the length of the derivation of \(I : \{p\}S\{q\}\). The base cases (skip, assignment, input and output) are immediate. We consider some rules:

- **sequential composition.** Consider a proof ending with an application of the sequential composition rule, yielding \(I : \{p\}S_1; S_2\{q\}\). Then we also have proofs of \(I : \{p\}S_1\{r\}\) and \(I : \{r\}S_2\{q\}\), for some \(r\). By induction hypothesis there exist proofoutlines \(pfo(I,p,S_1,r)\) and \(pfo(I,r,S_2,q)\). In particular, we have \((I \land \text{post}(S_1)) \rightarrow r\) and \((I \land r) \rightarrow \text{pre}(S_2)\). From this we deduce \((I \land \text{post}(S_1)) \rightarrow \text{pre}(S_2)\). Choosing \(\text{pre}(S_1; S_2) = \text{pre}(S_1)\) and \(\text{post}(S_1; S_2) = \text{post}(S_2)\) then gives us a proofoutline \(pfo(I,p,S_1; S_2,q)\).

- **while rule.** Consider a proof ending with an application of the while rule, yielding \(I :\{p\}\text{while} \ b \ do \ S_1 \ od \ p \land \lnot b\). Then we also have a proof of \(I : \{p \land b\}S_1\{p\}\). By induction hypothesis there exists a proofoutline \(pfo(I,p \land b,S_1,p)\). Choosing \(\text{pre}(\text{while} \ b \ do \ S_1 \ od) = p\) and \(\text{post}(\text{while} \ b \ do \ S_1 \ od) = p \land \lnot b\) then gives us a proofoutline \(pfo(I,p,S_1,od,q)\), because \((I \land p \land b) \rightarrow \text{pre}(S_1), (I \land \text{post}(S_1)) \rightarrow p\) and \((I \land p \land \lnot b) \rightarrow (p \land \lnot b)\).

- **input conditional.** Consider a proof ending with an application of the input conditional rule, yielding \(I : \{p\}\text{if} \ c??x \ then \ S_1 \ else \ S_2 \ fi\{p \land \lnot b\}\). Then there exists \(r\) such that we have a proof of \(I : \{p\}c??x; S_1\{q\}\) and of \(I : \{r\}S_2\{q\}\), and \((I \land p \land c = e) \rightarrow (I \land r)[c??? \cdot \bot/c???]\) is valid. By induction hypothesis there exist proofoutlines \(pfo(I,p,c??x; S_1,q)\) and \(pfo(I,r,S_2,q)\). Thus, there are \(\text{pre}(c??x; S_1), \text{post}(c??x; S_1), \text{pre}(c??x, S_1), \text{post}(c??x, S_1), \text{pre}(S_1), \text{post}(S_1),\) and \(\text{pre}(S_2), \text{post}(S_2)\) such that \((I \land p) \rightarrow \text{pre}(c??x; S_1), (I \land \text{post}(c??x; S_1)) \rightarrow q, (I \land \text{pre}(c??x; S_1) \rightarrow \text{pre}(c??x), (I \land \text{post}(c??x)) \rightarrow \text{pre}(S_1), (I \land \text{post}(S_1)) \rightarrow \text{post}(c??x; S_1), (I \land \text{pre}(c??x) \land c \neq e) \rightarrow (I \land \text{post}(c??x))[f(c)/x, c??? \cdot f(c)/c???], (I \land r) \rightarrow \text{pre}(S_2)\) and \((I \land \text{post}(S_2)) \rightarrow q\).
   Choosing \(\text{pre}(c??x; S_1) \rightarrow S_1\) else \(S_2\) fi = \(p\) and \(\text{post}(c??x; S_1) \rightarrow S_1\) else \(S_2\) fi = \(q\) then gives us a proofoutline \(pfo(I,p,\text{while} \ b \ do \ S_1 \ od,q)\), as can be seen by verifying \((I \land p \land c \neq e) \rightarrow (I \land \text{pre}(S_1))[f(c)/x, c??? \cdot f(c)/c???], (I \land p \land c = e) \rightarrow (I \land \text{pre}(S_2))[c??? \cdot \bot/c???]\) and \((I \land \text{post}(S_i)) \rightarrow q\) (\(i = 1,2\)) from the above.

The if-part is proven with induction on the structure of \(S\) (the input and output cases are omitted, being very similar to the assignment case):

- **S = skip** Suppose we have a proof outline \(pfo(I,p,S,q)\). According to the definition of a proofoutline we then have assertions \(\text{pre}(S)\) and \(\text{post}(S)\) such that the following hold: \((I \land p) \rightarrow \text{pre}(S), (I \land \text{post}(S)) \rightarrow q,\) and \((I \land \text{pre}(S)) \rightarrow \text{post}(S)\). We next show a derivation of \(I : \{p\}S\{q\}\):
• $S \equiv x := e$ Suppose we have a proof outline $pfo(I, p, S, q)$. We now have assertions $pre(S)$ and $post(S)$ such that the following hold: $(I \land p) \rightarrow pre(S)$, $(I \land post(S)) \rightarrow q$, and $(I \land pre(S)) \rightarrow post(S)[e/x]$. We next show a derivation of $I : \{p\}S\{q\}$:

(1) $I : \{q[e/x]\}S\{q\}$, by Axiom 2
(2) $I : \{post(S)[e/x]\}S\{q\}$, by Rule 8, (1) and $(I \land post(S)) \rightarrow q$, hence also
$I \land post(S)[e/x] \rightarrow q[e/x]$
(3) $I : \{pre(S)\}S\{q\}$, by Rule 8, (2) and $(I \land pre(S)) \rightarrow post(S)[e/x]$
(4) $I : \{p\}S\{q\}$, by Rule 8, (3) and $(I \land p) \rightarrow pre(S)$

• $S \equiv S_1; S_2$ Suppose we have a proof outline $pfo(I, p, S, q)$. We now have assertions $pre(S)$, $post(S)$, $pre(S_1)$, $pre(S_2)$, and $post(S_2)$ such that the following hold: $(I \land p) \rightarrow pre(S)$, $(I \land post(S)) \rightarrow q$, $(I \land pre(S)) \rightarrow pre(S_1)$, $(I \land post(S_1)) \rightarrow pre(S_2)$, and $(I \land post(S_2)) \rightarrow post(S)$.

From these facts we can easily derive $(I \land p) \rightarrow pre(S_1)$ and $(I \land post(S_1)) \rightarrow pre(S_2)$, and also $(I \land pre(S_2)) \rightarrow pre(S_1)$ and $(I \land post(S_2)) \rightarrow q$. This means we have proof outlines $pfo(I, p, S_1, pre(S_1))$ and $pfo(I, pre(S_2), S_2, q)$. Using the induction hypothesis twice and the rule for sequential composition we arrive at $\vdash I : \{p\}S\{q\}$.

• $S \equiv if \ b \ then \ S_1 \ else \ S_2 \ fi$ Suppose we have a proof outline $pfo(I, p, S, q)$. We now have assertions $pre(S)$, $post(S)$, $pre(S_1)$, $pre(S_2)$, and $post(S_2)$ such that the following hold: $(I \land p) \rightarrow pre(S)$, $(I \land post(S)) \rightarrow q$, $(I \land pre(S) \land b) \rightarrow pre(S_1)$, $(I \land pre(S) \land \neg b) \rightarrow pre(S_2)$, $(I \land post(S_1)) \rightarrow post(S)$, and $(I \land post(S_2)) \rightarrow post(S)$.

From these facts we derive $(I \land p \land b) \rightarrow pre(S_1)$ and $(I \land post(S_1)) \rightarrow q$, and also $(I \land p \land \neg b) \rightarrow pre(S_2)$ and $(I \land post(S_2)) \rightarrow q$. This means we have proof outlines $pfo(I, p \land b, S_1, q)$ and $pfo(I, p \land \neg b, S_2, q)$. Using the induction hypothesis twice and the rule for conditionals we arrive at $\vdash I : \{p\}S\{q\}$.

• $S \equiv \text{while} \ b \ do \ S_1 \ od$ Suppose we have a proof outline $pfo(I, p, S, q)$. We now have assertions $pre(S)$, $post(S)$, $pre(S_1)$, and $post(S_1)$ such that the following hold: $(I \land p) \rightarrow pre(S)$, $(I \land post(S)) \rightarrow q$, $(I \land pre(S) \land b) \rightarrow pre(S_1)$, $(I \land post(S_1)) \rightarrow pre(S)$, and $(I \land pre(S) \land \neg b) \rightarrow post(S)$.

From these facts we immediately derive the existence of a proof outline $pfo(I, pre(S) \land b, S_1, pre(S))$. Using the induction hypothesis we obtain $\vdash I : \{pre(S) \land b\}S_1\{pre(S)\}$, and hence, by application of the while rule, $\vdash I : \{pre(S)\}S\{pre(S) \land \neg b\}$. Finally, we apply the consequence rule, using the facts $(I \land pre(S) \land \neg b) \rightarrow q$ and $(I \land p) \rightarrow pre(S)$, which follow from the above, to obtain $\vdash I : \{p\}S\{q\}$.

• $S \equiv if \ c\??x \ then \ S_1 \ else \ S_2 \ fi$ Suppose we have a proof outline $pfo(I, p, S, q)$. We now have assertions $pre(S)$, $post(S)$, $pre(S_1)$, $pre(S_2)$, and $post(S_2)$ such that the following hold: $(I \land p) \rightarrow pre(S)$, $(I \land post(S)) \rightarrow q$, $(I \land pre(S) \land c \neq e) \rightarrow (I \land pre(S_1))[f(c)/x, c?? \cdot f(c)/c??], (I \land pre(S) \land c = e) \rightarrow (I \land pre(S_2))[c?? \cdot \bot/c??], (I \land post(S_1)) \rightarrow post(S)$, and $(I \land post(S_2)) \rightarrow post(S)$.

From these facts we derive $(I \land p) \rightarrow pre(S)$, $(I \land post(S)) \rightarrow q$, $(I \land pre(S)) \rightarrow pre(S)$, $(I \land pre(S_1)) \rightarrow pre(S_1)$, $(I \land post(S)) \rightarrow post(S)$, and $(I \land pre(S) \land c \neq e) \rightarrow (I \land pre(S_1))[f(c)/x, c?? \cdot f(c)/c??]$. This means we have a proof outline $pfo(I, p, c??x; S_1, q)$. Similarly, we derive $(I \land pre(S_2)) \rightarrow pre(S_2)$ and $(I \land post(S_2)) \rightarrow q$, giving us $pfo(I, pre(S_2), S_2, q)$. Using the induction hypothesis twice and $(I \land p \land c = e) \rightarrow (I \land pre(S_2))[c?? \cdot \bot/c??]$ the rule for input conditionals gives us $\vdash I : \{p\}S\{q\}$.
• \( S \equiv \text{while } c??x \text{ do } S_1 \text{ od} \) Suppose we have a proof outline \( pfo(I, p, S, q) \). We now have assertions \( \text{pre}(S), \text{post}(S), \text{pre}(S_1) \), and \( \text{post}(S_1) \) such that the following hold: \((I \land p) \rightarrow \text{pre}(S), (I \land \text{post}(S)) \rightarrow q, (I \land \text{pre}(S) \land c \neq \epsilon) \rightarrow (I \land \text{pre}(S_1))[f(c)/x, c?? \cdot f(c)/c??]\). (I \land \text{pre}(S) \land c = \epsilon) \rightarrow (I \land \text{post}(S))[c?? \cdot \bot/c??], \text{ and } (I \land \text{post}(S_1)) \rightarrow \text{pre}(S).

From the facts \((I \land \text{pre}(S)) \rightarrow \text{pre}(S), (I \land \text{pre}(S)) \rightarrow \text{pre}(S_1) \) and \((I \land \text{pre}(S) \land c \neq \epsilon) \rightarrow (I \land \text{pre}(S_1))[f(c)/x, c?? \cdot f(c)/c??]\) we derive a proof outline \( pfo(I, \text{pre}(S), c??x; S_1, \text{pre}(S)) \) (Somewhat more precisely: if we choose assertions \( \text{pre}(c??x) = \text{pre}(c??x; S) = \text{post}(c??) = \text{pre}(S) \), and \( \text{post}(c??x) = \text{pre}(S_1) = \text{pre}(S_1) \), all requirements of the proof outline are met. We use \( \text{pre}'(S_1) \) and \( \text{post}'(S_1) \) to distinguish from the assertions \( \text{pre}(S_1) \) and \( \text{post}(S_1) \) from the proof outline \( pfo(I, p, S, q) \). By induction hypothesis, we have a proof of \( I : \{\text{pre}(S)\}c??x; S_1[\text{pre}(S)] \). Now we can apply the input while loop rule, using \((I \land \text{pre}(S) \land c = \epsilon) \rightarrow (I \land \text{post}(S))[c?? \cdot \bot/c??] \), to obtain \( \vdash I : \{\text{pre}(S)\} S[\text{post}(S)] \), which after application of the consequence rule (using \((I \land p) \rightarrow \text{pre}(S) \) and \((I \land \text{post}(S)) \rightarrow q \) gives \( \vdash I : \{p\} S[q] \).

• \( S \equiv \text{repeat } S_1 \text{ until } c??x \) Suppose we have a proof outline \( pfo(I, p, S, q) \). We now have assertions \( \text{pre}(S), \text{post}(S), \text{pre}(S_1) \), and \( \text{post}(S_1) \) such that the following hold: \((I \land p) \rightarrow \text{pre}(S), (I \land \text{post}(S)) \rightarrow q, (I \land \text{pre}(S)) \rightarrow \text{pre}(S_1), (I \land \text{post}(S) \land c = \epsilon) \rightarrow (I \land \text{pre}(S))[c?? \cdot \bot/c??], \text{ and } (I \land \text{pre}(S) \land c \neq \epsilon) \rightarrow (I \land \text{post}(S))[f(c)/x, c?? \cdot f(c)/c??] \).

From \((I \land \text{pre}(S)) \rightarrow \text{pre}(S_1) \) we directly obtain a proof outline \( pfo(I, \text{pre}(S), S_1, \text{post}(S_1)) \), and from \((I \land \text{post}(S)) \rightarrow q \) and \((I \land \text{post}(S) \land c \neq \epsilon) \rightarrow (I \land \text{post}(S))[f(c)/x, c?? \cdot f(c)/c??] \) we obtain a proof outline \( pfo(I, \text{post}(S_1), c??x, q) \) (take \( \text{pre}(c??x) = \text{post}(S_1) \) and \( \text{post}(c??x) = \text{post}(S) \)). Thus, using the induction hypothesis we have proofs of \( I : \{\text{pre}(S)\} S_1[\text{post}(S)] \) and \( I : \{\text{post}(S_1)\} c??x[q] \). Now we apply the repeat rule using \((I \land \text{post}(S_1) \land c = \epsilon) \rightarrow (I \land \text{pre}(S))[c?? \cdot \bot/c??] \) to obtain a proof of \( I : \{\text{pre}(S)\} S[q] \). Finally, applying the consequence rule using \((I \land p) \rightarrow \text{pre}(S) \) gives the desired result.

Given lemma 1 it is not difficult to derive as a corollary from theorem 1 below the soundness of the parallel composition rule.

**Theorem 1** Given local proof outlines \( pfo(I, p_i, S_i, q_i) \) (\( 1 \leq i \leq n \)), a state \( \sigma \) such that \( \sigma \models I \land \bigwedge_i p_i \), and a computation \( \left([S_1 | ... | S_n], \sigma\right) \rightarrow^* \left([R_1 | ... | R_n], \sigma'\right) \) (\( \rightarrow^* \) denotes the reflexive, transitive closure of the transition relation \( \rightarrow \)), we have

1. \( \sigma' \models I \)
2. if \( R_i \) is before \((R, S_i) \) then \( \sigma' \models \text{pre}(R) \)
3. if \( R_i \) is after \((R, S_i) \) then \( \sigma' \models \text{post}(R) \)

**Proof** The proof proceeds with induction on the length of the computation.

The base case derives immediately from the validity of \((I \land p_i) \rightarrow \text{pre}(S_i) \) which follows from the local proof outlines \( pfo(I, p_i, S_i, q_i) \).

With respect to the induction step, we treat some cases:

1. \( \left([S_1 | ... | S_n], \sigma\right) \rightarrow^* \left([R_1 | ... | c??x; R_j | ... | R_n], \sigma''\right) \rightarrow \left([R_1 | ... | R_j | ... | R_n], \sigma'\right) \).

From the induction hypothesis we derive that \( \sigma'' \models I \), \( \sigma'' \models \text{pre}(R), \) if \( R_i = \text{before}(R, S_i) \) or \( \sigma' \models \text{post}(R), \) if \( R_i = \text{after}(R, S_i) \) \((i \neq j)\), and \( \sigma'' \models \text{pre}(c??x) \). Now, since the local assertion \( \text{pre}(R) \) \((\text{post}(R)) \) refers only to the variables of \( S_i \), it follows that \( \sigma' \models \text{pre}(R) \) \((\sigma' \models \text{post}(R)) \), for \( i \neq j \). Furthermore, it is not difficult to derive from the proof outline \( pfo(I, p_j, S_j, q_j) \) the validity of \((I \land \text{pre}(c??x) \land c \neq \epsilon) \rightarrow (I \land p)[f(c)/x, c?? \cdot f(c)/c??], \)

11
where \( p = \text{pre}(R) \) in case \( R_j = \text{before}(R, S_j) \), for some substatement \( R \) of \( S_j \), and \( p = \text{post}(R) \) in case \( R_j = \text{after}(R, S_j) \), for some substatement \( R \) of \( S_j \). We have that \( \sigma'' \models I \land \text{pre}(c??x) \land c \neq \epsilon, (\sigma'' \models c = \epsilon \text{ follows from the existence of the last transition}) \) and thus \( \sigma'' \models (I \land p)[f(c)/x, c?? \cdot f(c)/c??] \). Since \( \sigma' = \sigma''[f(\sigma'(c))/x, \sigma''(c??) \cdot f(\sigma''(c))/c??] \) we conclude that \( \sigma' \models (I \land p) \).

- \((S_1 \parallel \ldots \parallel S_n, \sigma) \rightarrow^* (R_1 \parallel \ldots \parallel R_n, \sigma'') \rightarrow (R_1 \parallel \ldots \parallel R_n, \sigma') \)

From the induction hypothesis we again derive \( \sigma' \models \text{pre}(R)(\text{post}(R)) \) for \( i \neq j \). Also by induction hypothesis we have \( \sigma'' \models I \land \text{pre}(\text{if } b \text{ then } S_1 \text{ else } S_2 \text{ fi}) \). Furthermore, by the last step we know \( \sigma'' \models b \), so by j's proof outline we derive \( \sigma'' \models \text{pre}(S_1) \), and hence, because \( \sigma'' = \sigma' \) also \( \sigma' \models \text{pre}(S_1) \) (the other choice possibility is completely analogous).

- \((S_1 \parallel \ldots \parallel S_n, \sigma) \rightarrow^* (R_1 \parallel \ldots \parallel \text{repeat } S_1 \text{ until } c??x; R_j \parallel \ldots \parallel R_n, \sigma'') \rightarrow (R_1 \parallel \ldots \parallel \text{repeat } S_1 \text{ until } c??x; R_j \parallel \ldots \parallel R_n, \sigma') \)

From the induction hypothesis we again derive \( \sigma' \models \text{pre}(R)(\text{post}(R)) \) for \( i \neq j \). Also by induction hypothesis we have \( \sigma'' \models I \land \text{pre}(\text{repeat } S_1 \text{ until } c??x) \). By j's proof outline we derive \( \sigma'' \models \text{pre}(S_1) \), and hence, because \( \sigma'' = \sigma' \) also \( \sigma' \models \text{pre}(S_1) \).

**Corollary 1** The parallel composition rule is sound.

**Proof** We show that any derivation ending in an application of the parallel composition rule leads to a valid formula. Suppose we have a derived \( I : \{\land_i p_i\}[S_1 \parallel \ldots \parallel S_n][\land_i q_i] \), using the parallel composition rule in the last step. Then, for all \( i \), we have a derivation of \( I : \{p_i\}S_i[q_i] \). By lemma 1 we have proofoutlines \( \text{pfo}(I, p_i, S_i[q_i]) \) for all \( i \).

Now consider a state \( \sigma \) such that \( \sigma \models I \land \land_i p_i \). Let \( CS \) be a finite terminating computation sequence of \( [S_1 \parallel \ldots \parallel S_n] \), of which \( \sigma' \) is the second component of the last configuration. According to theorem 1, we have that \( \sigma' \models I \land \land_i \text{post}(S_i) \), and hence, using \( (I \land \text{post}(S_i)) \rightarrow q_i \) from the proofoutline of \( S_i \) also \( \sigma' \models I \land \land_i q_i \). We therefore conclude \( \models I : \{\land_i p_i\}[S_1 \parallel \ldots \parallel S_n][\land_i q_i] \).

6 Completeness

We prove completeness in the sense that every valid global correctness formula is derivable. Let \( I : \{\phi\}P(\psi) \) be a valid correctness formula, with \( P = [S_1 \parallel \ldots \parallel S_n] \). We will sketch a proof of the derivability of \( I : \{\phi\}P(\psi) \). Let \( \bar{v} \) be the variables of \( P \) (both the program variables and those input/output variables \( c??, c!! \)), for which \( c \) is a channel of \( P \). By \( \bar{v} \), we denote the variables of \( S_i \). To be more precise, \( \bar{v} \), consists of all the program variables of \( S_i \) and the input (output) variables \( c??, c!! \) with \( c \) an input (output) channel of \( S_i \). Finally, the set of input/output variables of \( P \) we denote by \( \bar{c} \) (so \( \bar{c} \) consists of the variables \( c??, c!! \), with \( c \) a channel of \( P \)).

We first construct local proof outlines of the components \( S_i \) by introducing local assertions \( \text{pre}(R) \) and \( \text{post}(R) \), for all substatements \( R \) of \( S_i \). Roughly speaking, an assertion \( \text{pre}(R) \) characterizes all those intermediate states of a computation of the program \( P \) such that process \( i \) is about to execute \( R \) (or has just finished executing \( R \), in case of \( \text{post}(R) \)). Let \( \phi' = \phi \land \bar{v} = \bar{z} \), where \( \bar{z} \) are new variables which are introduced to 'freeze' the initial values of \( \bar{v} \).

**Definition 12** For \( R \) a substatement of \( S_i \) we define:
$\sigma \models \text{pre}(R)$ iff $\exists \sigma', \sigma'', R_1, \ldots, R_n$ such that $\sigma' \models I \land \phi'$

$$<\{S_1 \parallel \ldots \parallel S_n\}, \sigma'> \rightarrow^* <\{R_1 \parallel \ldots \parallel R_n\}, \sigma''>$$

$\sigma(\bar{v}_i) = \sigma''(\bar{v}_i)$ and $\sigma(\bar{z}) = \sigma''(\bar{z})$

$R_i = \text{before}(R, S_i)$

and

$\sigma \models \text{post}(R)$ iff $\exists \sigma', \sigma'', R_1, \ldots, R_n$ such that $\sigma' \models I \land \phi'$

$$<\{S_1 \parallel \ldots \parallel S_n\}, \sigma'> \rightarrow^* <\{R_1 \parallel \ldots \parallel R_n\}, \sigma''>$$

$\sigma(\bar{v}_i) = \sigma''(\bar{v}_i)$ and $\sigma(\bar{z}) = \sigma''(\bar{z})$

$R_i = \text{after}(R, S_i)$

Next we define the following global invariant $I'$:

**Definition 13** Let $I'$ be an assertion such that:

$\sigma \models I'$ iff $\exists \sigma', \sigma'', R_1, \ldots, R_n$ such that $\sigma' \models I \land \phi'$

$$<\{S_1, \ldots, S_n\}, \sigma'> \rightarrow^* <\{R_1, \ldots, R_n\}, \sigma''>$$

$\sigma(\bar{z}) = \sigma''(\bar{z})$ and $\sigma(\bar{z}) = \sigma''(\bar{z})$

In words, $I'$ asserts that $\sigma$'s valuation of the input/output variables of $P$ can actually be obtained by some computation of $[S_1 \parallel \ldots \parallel S_n]$ starting from a state satisfying $I \land \phi'$.

By standard techniques [TZ88], $I'$, $\text{pre}(R)$ and $\text{post}(R)$ can be shown to be expressible in our assertion language such that the variables of $\text{pre}(R)$ and $\text{post}(R)$ ($R$ a substatement of $S_i$) are among the variables $\bar{v}_i$ and $\bar{z}$, and the variables of $I'$ are among the variables $\bar{c}$ and the variables $\bar{z}$.

In order to prove that the assertions $\text{pre}(R)$, $\text{post}(R)$ and $I'$ as above, with $R$ a substatement of $S_i$, define a proof outline of $S_i$ we need the following lemma:

**Lemma 2 (merging lemma)** Let, for $i = 1, \ldots, n$, be given the computations

$$<\{S_1 \parallel \ldots \parallel S_n\}, \sigma> \rightarrow^* <\{R_i \parallel \ldots \parallel \}, \sigma_i>$$

Then for any computation

$$<\{S_1 \parallel \ldots \parallel S_n\}, \sigma> \rightarrow^* <\{R'_1 \parallel \ldots \parallel R'_n\}, \sigma'>$$

such that $\sigma'$ and $\sigma_i$ agree with respect to the input/output variables of $S_i$, there exists a computation

$$<\{S_1 \parallel \ldots \parallel S_n\}, \sigma> \rightarrow^* <\{R_1 \parallel \ldots \parallel R_n\}, \sigma''>$$

with $\sigma''(\bar{v}_i) = \sigma_i(\bar{v}_i)$ ($i = 1, \ldots, n$).

The above lemma follows in a straightforward manner from the fact that the input/output behaviour of a statement $S_i$ as given by its input/output variables completely determines its local behaviour up to internal, i.e. non-communication actions ($S_i$ being deterministic). A formal proof is given below. Meanwhile, it is worthwhile to point out that the above lemma holds because of the recording of tests on an empty buffer. Consider the following two statements:

$$S = \text{if } c???x \text{ then } d!!0; R_1 \text{ else } d!!0; c???x; R_2 \text{ fi}$$

13
Given an initial state with empty buffers $c$ and $d$, there exists a computation of $[S \parallel S']$ which reaches $R_1$ and there exists a computation of $[S \parallel S']$ which reaches $R_1'$. But there does not exist a computation which reaches both $R_1$ and $R_1'$. This does not invalidate the merging lemma, because there is no computation ending in a state which agrees with the two computations with respect to the input/output variables; for the first computation reaches a state $\sigma$ with $\sigma(c??) = \sigma(\text{c!!}) = \sigma(d!!) = (0)$, $\sigma(d??) = (\bot, 0)$ and the second computation reaches a state $\sigma'$ with $\sigma'(c??) = (\bot, 0)$, $\sigma'(d??) = \sigma'(\text{d!!}) = \sigma'(\text{c!!}) = (0)$. If we would not record test on empty buffers there is a computation ending in a state which agrees with the two computations (take one of them), which would invalidate the merging lemma.

Proof of merging lemma Let $|\sigma(c??)| (|\sigma(\text{c!!})|)$ denote the length of the sequence that is assigned by $\sigma$ to channel variable $c$? (c!!). Note that we also take into account the special symbol $\bot$. We prove the merging lemma with induction on $\Sigma_{c \in IO(|\sigma'(c??)| + |\sigma'(\text{c!!})|)}$, that is to say the total number of all input and output actions that have taken place in the computation $CS \stackrel{def}{=} ([S_1 \parallel \ldots \parallel S_n], \sigma) \rightarrow^* ([R_1 \parallel \ldots \parallel R_n], \sigma')$ from the lemma.

* $\Sigma_{c \in IO(|\sigma'(c??)| + |\sigma'(\text{c!!})|)} = 0$: then for all $i$, $\sigma'(c??) = \sigma'(\text{c!!}) = \epsilon$. Hence, $\sigma_i(c??) = \sigma_i(\text{d!!}) = \epsilon$, where $c??$, $d!! \in IO$. So, for every $i$, $CS_i \stackrel{def}{=} ([S_1 \parallel \ldots \parallel S_n], \sigma) \rightarrow^* ([\ldots \parallel R_i \parallel \ldots], \sigma_i)$ contains $0$ $i$-IO transitions. Therefore, we can leave out all non-i transitions from $CS_i$ (updating the intermediate global states in order to obtain a correct global computation) for all $i$, obtaining $CS_i'$, and then "glue" all $CS_i'$ together, executing them one after another, again replacing the global states accordingly. Evidently, this gives the desired computation.

* $\Sigma_{c \in IO(|\sigma'(c??)| + |\sigma'(\text{c!!})|)} > 0$: Suppose that the last IO-transition in $CS$ was due to execution of an input $c??x$ in process i (replacing $c??x$ by d!!e is completely analogous). Thus, $CS$ has the following form:

$$\langle [S_1 \parallel \ldots \parallel S_n], \sigma \rangle \rightarrow^* \langle [\hat{R}_1 \parallel \ldots \parallel c??x; \hat{R}_1' \parallel \ldots \parallel \hat{R}_n'], \hat{\sigma} \rangle \rightarrow^* \langle [\hat{R}_1' \parallel \ldots \parallel \hat{R}_n'], \hat{\sigma}' \rangle$$

Define $CS'$ as the prefix of $CS$ up to and including the configuration $\langle [\hat{R}_1' \parallel \ldots \parallel c??x; \hat{R}_1' \parallel \ldots \parallel \hat{R}_n'], \hat{\sigma} \rangle$, i.e. up to the point where $c??x$ is about to be executed. By lemma 3 we know that there exists $CS'_i = ([S_1 \parallel \ldots \parallel S_n], \sigma) \rightarrow^* ([\ldots \parallel \hat{R}_i' \parallel \ldots], \sigma''_i)$ where $\sigma''_i(\hat{v}_j) = \sigma_i(\hat{v}_j)$, and all transitions after the input $c??x$ are internal i-transitions. Define $CS''_i$ as the prefix of $CS'_i$ up to and including the configuration $\langle [\ldots \parallel \hat{R}_i' \parallel \ldots], \sigma''_i \rangle$.

Then, we can use the induction hypothesis, using the existence of $CS_j$, for $j \neq i$, $CS''_i$ and $CS'$, yielding a computation sequence $CS' : ([S_1 \parallel \ldots \parallel S_n], \sigma) \rightarrow^* ([R_1 \parallel \ldots \parallel R_n], \sigma)$ with $\sigma(\hat{v}_j) = \sigma_j(\hat{v}_j)$, $j \neq i$ and $\sigma(\hat{v}_i) = \sigma''_i(\hat{v}_i)$.

Now we can extend $CS'$ with the transition sequence $CS_i - CS''_i$, again adjusting the global states accordingly, to get the desired run.

□

Lemma 3 Suppose there exists a computation sequence $([S_1 \parallel \ldots \parallel S_n], \sigma) \rightarrow^* ([\ldots \parallel R_i \parallel \ldots], \sigma_i)$, Suppose furthermore there exists a c.s. $([S_1 \parallel \ldots \parallel S_n], \sigma) \rightarrow^* ([\ldots \parallel c??x; R_i' \parallel \ldots], \sigma''_i) \rightarrow^* ([R_i' \parallel \ldots \parallel R_i' \parallel \ldots \parallel R_n], \sigma')$ such that $\sigma$ agrees with $\sigma_i$ on the input/output variables of process i, and furthermore $c??x$ is the last input/output command that is executed. Then, there exists a c.s. $([S_1 \parallel \ldots \parallel S_n], \sigma) \rightarrow^* ([\ldots \parallel c??x; R_i' \parallel \ldots], \sigma'_i) \rightarrow^* ([\ldots \parallel R_i' \parallel \ldots], \sigma''_i)$ where $\sigma''_i(\hat{v}_j) = \sigma_i(\hat{v}_j)$, $c??x$ is the last input/output command that is executed and after $c??x$ only i-transitions occur. (Again, this lemma also holds in the case that $c??x$ is replaced by d!!e.)
Proof By the fact that \( \sigma \) agrees with \( \sigma' \) with respect to the input/output variables of process \( i \), we know that the last \( i \)-IO-transition in the first transition sequence is due to execution of \( c??x \) in \( S_i \). This is because the ordering of input and output actions is uniquely determined by the value of the input/output variables of a (deterministic) process. In order to obtain from this computation sequence the desired computation sequence, all we have to do is dismiss all subsequent non-\( i \) transitions from it, adjusting the states accordingly. Note that this is possible because none of the subsequent \( i \)-transitions depends on any non-\( i \) transition that is being removed. □

Now we are ready for the following key lemma of the completeness proof:

Lemma 4 The assignment of local assertions \( \text{pre}(R) \) and \( \text{post}(R) \) to any substatement \( R \) of \( S_i \) defines a proof outline \( \text{pfo}(I', \text{pre}(S_i), S_i, \text{post}(S_i)) \).

Proof We only illustrate the following case from definition 11. Consider condition 5: \((I' \land \text{pre}(R) \land c \neq \epsilon) \rightarrow (I' \land \text{post}(c??x))[f(c)/x, c?? \cdot f(c)/c??] \), with \( c??x \) occurring in \( S_i \). Suppose for some \( \sigma \) we have \( \sigma \models I' \land \text{pre}(R) \land c \neq \epsilon \). By definition of \( \text{pre}(c??x) \) and \( I' \) there exist computations

\[
\langle [S_1 \parallel \ldots \parallel S_n], \sigma' \rangle \rightarrow^* \langle [R_{1} \parallel \ldots \parallel R_n], \sigma_i \rangle
\]

and

\[
\langle [S_1 \parallel \ldots \parallel S_n], \sigma' \rangle \rightarrow^* \langle [R'_{1} \parallel \ldots \parallel R'_n], \sigma'' \rangle
\]

such that \( \sigma' \models I \land \phi' \land \sigma(\bar{v}_i) = \sigma(\bar{v}_i), \sigma(\bar{v}) = \sigma(\bar{v}), \sigma(\bar{e}) = \sigma''(\bar{e}), \) and \( \sigma(\bar{e}) = \sigma''(\bar{e}) \). Note that the introduction of the freeze variables \( \bar{e} \) and the additional conjunct \( \theta = \bar{e} \) of \( \phi' \) allows us to assume without loss of generality that the above computations start indeed with the same initial state.

Now, since the states \( \sigma_i \) and \( \sigma'' \) agree with respect to the input/output variables of \( S_i \), we have by lemma 2 that there exists a computation

\[
\langle [S_1 \parallel \ldots \parallel S_n], \sigma' \rangle \rightarrow^* \langle [R'_{1} \parallel \ldots \parallel R'_n], \sigma'' \rangle
\]

such that \( \sigma_i(\bar{v}_i) = \sigma''(\bar{v}_i) \). Furthermore, since \( \sigma \) and \( \sigma'' \) agree with respect to the input/output variables (this is because \( \sigma(\bar{v}_i) = \sigma(\bar{v}_i), \sigma''(\bar{v}_i) = \sigma''(\bar{v}_j) \) for \( i \neq j \) and \( \sigma'' \) agrees with \( \sigma \) with respect to \( \bar{e} \) and \( \sigma(c) \neq \epsilon \), it also follows that \( \sigma''(c) \neq \epsilon \), so that the input action \( c??x \) is indeed enabled in \( \sigma'' \). Thus we have by definition of \( I' \) and \( \text{post}(c??x) \) that \( \sigma''(\langle f(c)/x, \sigma''(c) || f(c)/c?? \rangle \rightleftharpoons I' \land \text{post}(c??x), \text{that is, } \sigma'' \models (I' \land \text{post}(c??x))[f(c)/x, c?? \cdot f(c)/c??] \). From this we conclude that \( \sigma \models (I' \land \text{post}(c??x))[f(c)/x, c?? \cdot f(c)/c??] \) (note that \( \sigma \) and \( \sigma'' \) agree with respect to the variables \( \bar{e} \) and \( \bar{v}_i \)). □

By the above lemma and lemma 1, we thus infer \( \vdash I' : \{ \text{pre}(S_i) \} S_i \{ \text{post}(S_i) \} \), for all \( i \). So, using the parallel composition rule, we derive \( \vdash I' : \{ \bigwedge_i \text{pre}(S_i) \} P \{ \bigwedge_i \text{post}(S_i) \} \).

To proceed we need the following propositions:

Proposition 1 We have \( \models (I \land \phi') \rightarrow (I' \land \bigwedge_i \text{pre}(S_i)) \).

The above proposition follows immediately from the definition of \( I' \) and \( \text{pre}(S_i) \).

Proposition 2 We have \( \models (I' \land \bigwedge_i \text{post}(S_i)) \rightarrow \psi \).

Proof Suppose \( \sigma \models (I' \land \bigwedge_i \text{post}(S_i)) \), then by definition of \( I' \) and \( \text{post}(S_i) \) we have a computation \( \langle [S_1 \parallel \ldots \parallel S_n], \sigma' \rangle \rightarrow^* \langle [R'_{1} \parallel \ldots \parallel R'_n], \sigma'' \rangle \) and, for all \( i \), a computation \( \langle [S_i \parallel \ldots \parallel S_n], \sigma' \rangle \rightarrow^* \langle [\ldots \parallel E \parallel \ldots \parallel], \sigma \rangle \) such that \( \sigma' \models I \land \phi' \), \( \sigma(\bar{v}_i) = \sigma(\bar{v}_i) \) and \( \sigma(\bar{e}) = \sigma''(\bar{e}) \) (again we may assume
a common initial state). Hence, by lemma 2 we have a computation \(<[S_1 \| \cdots \| S_n], \sigma'>\rightarrow^* ([E \| \cdots \| E], \sigma''') such that \(\sigma'''(\hat{v_i}) = \sigma_i(\hat{v_i})\). So we have a terminating computation sequence of \([S_1 \| \cdots \| S_n]\), starting in a state \(\sigma'\) that satisfies \(\sigma' \models I \land \phi\) (even \(\sigma' \models I \land \phi'\)), and ending in \(\sigma'''\), hence by \(\models I : \{\phi\}P\{\psi\}\) we derive \(\sigma''' \models \psi\) and hence \(\sigma \models \psi\) □

**Proposition 3** We have \(\models I' \rightarrow I\).

This proposition follows immediately from the definition of \(I'\) and the validity of \(I : \{\phi\}P\{\psi\}\). We conclude with the following corollary:

**Corollary 2** We have \(\vdash I : \{\phi\}P\{\psi\}\).

**Proof** By an application of the consequence rule, using the above propositions we obtain the derivability of \(I : \{\phi'\}P\{\psi\}\). An application of the substitution rule (substituting \(\hat{v}\) for \(\hat{z}\)) then gives \(\vdash I : \{\phi\}P\{\psi\}\) □

## 7 Extending synchronization

In the programming language discussed so far synchronization is modeled by the input statement \(c??x\) (note that input commands as tests in choice and while constructs model only communication and do not incorporate synchronization). However since an input command \(c??x\) only checks for the channel \(c\) (and suspends in case its corresponding buffer is empty) its proper execution implicitly requires a predictable and determinate environment which is guaranteed to send eventually along channel \(c\).

In order to increase the capability of a deterministic process to respond to an indeterminate environment we introduce a natural generalization of the input command: the input command \(C??x\), with \(C\) a non-empty finite set of channels, which allows a process to scan the channels of \(C\) simultaneously. More precisely, the execution of an input command \(C??x\) consists of selecting non-deterministically a non-empty channel \(c \in C\), and reading a value from \(c\) (which is then stored in \(x\)). The execution of \(C??x\) suspends when all the channels of \(C\) are empty. Formally, we have the following new syntax of a sequential process:

\[
S ::= \text{skip} \quad \text{or} \quad x := e \quad C??x \mid \text{clause} \quad S_1 ; S_2 \quad \text{if } b \text{ then } S_1 \text{ else } S_2 \text{ fi} \quad \text{while } b \text{ do } S \text{ od} \quad \text{if } c??x \text{ then } S_1 \text{ else } S_2 \text{ fi} \quad \text{while } c??x \text{ do } S \text{ od} \quad \text{repeat } S \text{ until } c??x
\]

where \(C\) denotes a (non-empty) finite set of channels. The (simple) input command \(c??x\) will be interpreted as an abbreviation of \(\{c\}??x\). For technical convenience we only allow simple input commands to occur as tests in the choice and while construct, although the proof theory to be presented below can easily be extended to the general case.

It is not so difficult to see that recording for each channel the values sent and received, respectively, is not sufficient anymore to determine the local behaviour of a process completely. Consider for
example the process

\{c, d\}??x; if x = 0 then \{c, d\}??x; R_1 else \{c, d\}??x; x := x + 1; R_2 fi

Suppose that the value 0 has been sent first along channel c and that the value 1 has been sent first along d. Recording only for the channels c and d the values sent and received, respectively, we would not be able to determine whether the above process is about to execute R_1 or R_2; namely, either the process could have read first from c and then from d or vica versa.

In order to be able to determine the local behaviour of a process we introduce for each process \(S_i\) (of a program \(P = [S_1 || \ldots || S_n]\)) a local channel variable \(h_i\) which records the sequence of channels that have been selected in a generalized input command. Axiomatically, this is formalized as follows. Let \(P = [S_1 || \ldots || S_n]\). A local correctness formula is of the form \(I : \{p\}R(q)\), with \(R\) a substatement of \(S_i\) \((i = 1, \ldots, n)\), and I is an assertion which is not allowed to refer to the program variables of \(P\) (so it is allowed to refer to the channel variables), \(p\) and \(q\) are assertions which are allowed to refer only to the set of variables of \(S_i\), which now additionally contains, besides its program variables and its input/output variables, the channel variable \(h_i\) (the input variables of a statement \(S\) consist of all those variables \(c\) for which there exists a substatement \(C??x\) of \(S\) such that \(c \in C\)). We have the following proof rule for an input command \(C??x\):

\[
(I \land p \land c \neq \epsilon) \rightarrow (I \land q)[f(c)/x, c? \cdot f(c)/c?, h_i \cdot c/h_i] \\
I : \{p\}C??x(q)
\]

Here \(c \in C\), and \(C??x\) is understood to occur in \(S_i\) of the program \(P = [S_1 || \ldots || S_n]\). Since we allow a channel variable \(h_i\) to occur in the global invariant \(I\) we have to include \(I\) in the scope of the newly added substitution \([h_i \cdot c/h_i]\), which models appending the channel \(c\) to the sequence of channels \(h_i\). We assume in the above rule that \(C\) is not a singleton set. For \(\{c\}??x\), that is \(c??x\), we have the same proof rule as before:

\[
(I \land p \land c \neq \epsilon) \rightarrow (I \land q)[f(c)/x, c? \cdot f(c)/c?] \\
I : \{p\}C??x(q)
\]

For the formal justification of the resulting proof system we have to include in a state a valuation of the new channel variables \(h_i\). The semantics of an input command \(C??x\) is then described in terms of the input/output variables and the corresponding channel variable. For \(C??x\) in \(S_i\) of the program \(P = [S_1 || \ldots || S_n]\) we have the following semantic description corresponding to the above proof rule:

\[
([[\ldots || C??x; S || \ldots], \sigma) \rightarrow ([[\ldots || S || \ldots], \sigma\{\sigma(c) \cdot d/c\?, d/x, \sigma(h_i) \cdot c/h_i\})
\]

provided \(\sigma(c) \neq \epsilon\) and \(d = f(\sigma(c))\), for \(c \in C\). Again, here \(C\) is assumed to be different from a singleton set. Input commands of the form \(\{c\}??x\), that is \(c??x\), are treated as before: they do not require an additional update to the channel variable \(h_i\).

It should be noted that the additional information recorded by the channel variables still provides an abstraction from histories as sequences of communication events, where a communication event is of the form \(c??d\) or \(d??c\), indicating that the value \(d\) has been read from channel \(c\), or that \(d\) has been sent along \(c\).

Soundness and completeness can be proved in essentially the same way as before. In the completeness proof both the local assertions \(\text{pre}(R), \text{post}(R)\) and the global invariant \(I\) additionally specify the valuation of the new channel variables. Note that the set of local variables of \(S_i\) (belonging to the program \(P = [S_1 || \ldots || S_n]\)) now include the channel variable \(h_i\). The global invariant now specifies the values of the variables \(\sigma\) which, besides the usual input/output variables, include the channel variables \(h_i\). The main point of the completeness proof consists of the observation that also in this new case the merging lemma holds, which follows easily from the observation that
the input/output variables of a process together with its channel variable completely determine its local behaviour.

8 Conclusion

We have shown that it is possible to obtain a compositional proof theory for distributed systems composed of asynchronously communicating processes, using input/output variables only to reason about communication, provided the programming language considered is in essence deterministic. In spite of this determinism, by providing constructs which allow a process to test the contents of a buffer we obtain a quite powerful language in which one can describe processes with the ability to respond to an indeterminate environment.

Nevertheless, it seems possible to extend the degree of nondeterminism available, as is indicated in section 7. Therefore, it is interesting to investigate the expressivity of the language thus obtained, in particular as compared to common nondeterministic languages, such as CSP.

First of all, the nondeterminism introduced by the generalized input command can be seen to be of a limited nature. This is because a process is not able to choose between subsequent actions (following the generalized input command) depending on which of the channels was read. In other words, the generalized input command could be viewed as a CSP guarded command with boolean guard parts set to true and empty bodies.

In the following we will indicate how, via coding messages by tagging them with the channel name of the channel over which they are sent, it is possible to express the CSP guarded command \([c_1, \ldots, c_n] \rightarrow S_1[\ldots][c_n, \ldots] \rightarrow S_n\) in our —extended— language, provided that all channels are distinct.

Suppose that, instead of the normal values \(v\), now messages of type \(v_c\) are transmitted, where \(c\) refers to the channel over which \(v\) is sent. Also assume the operations tag and val which yield the channel and value of a message. Then we can write the above statement as follows:

\[
\begin{align*}
\{c_1, \ldots, c_n\} ??x \text{ if } tag(x) = c_1 \text{ then } x_1 := \text{val}(x); S_1 \text{ else }  \\
&\quad \vdots  \\
&\quad \text{if } tag(x) = c_n \text{ then } x_n := \text{val}(x); S_n \text{ else skip fi}
\end{align*}
\]

Of course, the introduction of this new type of message along with the operations tag and val has its price: we are no longer able to reason on the same abstraction level as that of the (original, i.e. CSP) program, because we now have to hack around unravelling messages. This provides an interesting trade-off between aiming for compositionality using as little history information as possible on one hand, and staying as close to the abstraction level of the programming language on the other hand.
